#### Abstract

The synthesis of a library of halogenated rocaglate derivatives belonging to the flavagline class of natural products, of which silvestrol is the most prominent example, is reported. Their antiviral activity and cytotoxicity profile against a wide range of pathogenic viruses, including hepatitis E, Chikungunya, Rift Valley Fever virus and SARS-CoV-2, were determined. The incorporation of halogen substituents at positions $4^{\prime}, 6$ and 8 was shown to have a significant effect on the antiviral activity of rocaglates, some of which even showed enhanced activity compared to CR-31-B and silvestrol.

flavaglines was studied for the natural product silvestrol (2a) and 1 -O-formylglafoline (1d). The excellent broadband antiviral activity of silvestrol (2a) was substantiated for highly pathogenic Ebola virus, ${ }^{7}$ as well as Zika virus, Hepatitis E virus (HEV) and viruses from the Coronaviridae and Picornaviridae family without pronouced cytotoxic effects for immortalized cell lines (Huh-7 and MRC-5). ${ }^{8}$ Translation initiation is a key process in viral proliferation. Because RNA viruses do not encode their own translational machinery, they rely on host protein synthesis. In the past, targeting the translation machinery of the host has been extensively studied and proposed as a therapeutic strategy for the treatment of viral infections. It is widely accepted that rocaglates exert their biological activity by stimulation of eIF4Af-RNA clamping. ${ }^{9}$ The eukaryotic initiation factor 4 a (eIF4A) is an ATPdependent RNA helicase, responsible for unwinding the secondary structure of mRNAs. Flavaglines force an engagement between eIF4A and RNA that prevents eIF4A from participating in the ribosome-recruitment step of translation. Recently, Iwasaki and co-workers resolved the structure of the human complex composed of eIF4A1, AMPPNP, rocaglamide $\mathbf{l b}$ and polypurine RNA, providing the molecular basis of

## - INTRODUCTION

Rocaglates are natural products that belong to the flavaglines, a natural product class with more than 100 members to date. ${ }^{1-3}$ They are found in several tree species of the genus Aglaia (Meliaceae) that grow in subtropical and tropical forests of Southeast Asia, Northern Australia and the Pacific region. ${ }^{4}$

The first rocaglate extracts collected revealed significant activity against P-388 lymphatic leukemia in CDF1 mice and inhibitory activity in vitro against cells derived of human epidermoid carcinoma of the nasopharynx ( $\kappa \mathrm{B}$ cells). The antileukemic effect was attributed to the $1 H$-cyclopenta $[b]$ benzofurans rocagloic acid (1a, Figure 1) and rocaglamide (1b). ${ }^{5}$ Later, antiviral properties against the Newcastle disease virus (NDV) were reported ${ }^{6}$ and the biological target of

rocaglamide RNA sequence selectivity. From these X-ray studies it was found that in particular the dimethoxysubstituted aromatic ring A in $\mathbf{1 b}$ is directed toward the polypurine RNA. As such, ring $A$ is stacked with the adenine base of A7 and guanine base of G8 nearly in parallel. ${ }^{10}$
Synthetic efforts had led to new rocaglate variants and derivative (-)-CR-31-B (1c) has to be noted as it was also found to inhibit the replication of Zika-, Lassa-, Crimean Congo hemorrhagic fever virus and Coronaviridae family members. ${ }^{11-13}$ It was precisely this promising biological potential of rocaglates that triggered synthetic programs culminating in the first total synthesis by Trost et al. in $1990^{14}$ and follow-up synthetic programs by the groups of Désaubry, ${ }^{15-17}$ Porco, ${ }^{18,19}$ Tremblay, ${ }^{20}$ Burns, ${ }^{21}$ Ishibashi ${ }^{22}$ and Reich ${ }^{23}$ that provided rocaglate-derived compound libraries.

The majority of these studies primarily focused on the substitution of the methoxy groups at C6 and C4' and variation of the amide moiety. Both showed a profound effect on biological activity. Unsurprisingly, several halogenated rocaglates were also part of these libraries, as halogens are of great importance in medicinal chemistry. They give, in most cases, advantages to biophysical and -chemical properties of related compounds. Halogen substitution can enhance metabolic stability, lipophilicity and electronegativity. Moreover, introduction of halogen substituents can also provide halogen bonding (XB), which might lead to enhanced activity. ${ }^{24-26}$ In these preliminary studies, it was revealed that chlorine at C6 and a chlorine or bromine substituent at C 4 ' lead to a significant improvement in the inhibition of translation initiation. ${ }^{14-16,20,27,28}$ However, the possible impact of the small and highly electronegative fluorine atom as a substituent at C 6 or $\mathrm{C} 4^{\prime}$ is so far unknown. Furthermore, no derivatives halogenated at the C 8 position have been reported to date.

Consequently, we initiated a program to synthesize and biologically evaluate a library of so far unknown halogenated rocaglate derivatives and tested them against several emerging RNA viruses, including HEV, Chikungunya (CHIKV), Rift Valley fever (RVFV) and SARS-CoV-2 viruses. As part of this program, we also aimed to identify the most practical synthetic route among several options for accessing the target derivatives.

## - RESULTS AND DISCUSSION

General Considerations on the Syntheses. To date, the majority of rocaglate syntheses are based on a biomimetic approach starting from 3-hydroxyflavones (flavonol) and cinnamic acid derivatives, first described by Porco and coworkers in 2004. ${ }^{29}$ This process first involves UV lightmediated $[3+2]$-cycloaddition via an excited-state intramolecular proton transfer leading to the aglain core. Subsequently, skeletal rearrangements via a ketol shift and anti-selective reduction of the resulting ketone lead to the cyclopenta $[b]$ benzofuran core present in the rocaglates. Excellent substrate selection and high diastereoselectivity for the establishment of the five stereocenters in only three steps are compelling reasons for the superiority of this route.

Surprisingly, synthetic access to the required $5,7,4^{\prime}$ substituted flavonols still poses a major challenge. In previous studies on flavaglines, the flavonols were most commonly prepared via an Algar-Flynn-Oyamada (AFO) reaction ${ }^{14,22}$ or alternatively a Baker-Venkataraman synthesis. ${ }^{20,22,30}$

The first route represents an oxidative cyclization of the corresponding chalcone with $\mathrm{NaOH}, \mathrm{KOH}$ or $\mathrm{K}_{2} \mathrm{CO}_{3}$ in combination with hydrogen peroxide (Scheme 1, Route A).

## Scheme 1. Synthetic Approaches to Rocaglate Derivatives with $5,7,4^{\prime}$-Substituted Flavonols as Key Intermediates and Structure of Aurones

Although this biomimetic approach allows for rapid access to flavonols, its substrate scope is however rather restricted. In particular, electron-donating substituents at C5 and C7 or electron-withdrawing substituents at $\mathrm{C} 4^{\prime}$ favor the formation of the corresponding aurone instead of the flavonoid. ${ }^{31,32}$ It should be noted, however, that in principle an alternative type of cyclization to the aurone skeleton is conceivable and possible.
The Baker-Venkataraman synthesis (Scheme 1, Route B) ${ }^{20}$ requires a larger number of steps but is supposedly more versatile with respect to substrate scope, as the different electronic properties of the substituents at C5 and C7 have little effect on the formation of flavonol.

The synthesis commenced from the corresponding ohydroxyl acetophenones. A Rubottom oxidation sequence leads to the $\alpha$-hydroxyacetophenones from which the bisbenzoates are formed by esterification. Depending on the desired substitution pattern on the $B$ ring, various benzoic acid or benzoyl chloride derivatives can be used. ${ }^{20,22}$ Next, the sequence proceeds through a base-mediated Baker-Venkataraman rearrangement, followed by acid-catalyzed condensation and saponification of the enol ester that yields the flavonol. However, the aforementioned reaction sequence involves harsh basic and acidic conditions, which can limit the application of some protecting and functional groups.

Synthesis of Rocaglates Based on the BakerVenkataraman Rearrangement. To investigate the influence of halogen substituents at $\mathrm{C}^{\prime}$, we resorted to the BakerVenkataraman route, since the electron-withdrawing effect of fluorine, chlorine and bromine in the AFO reaction strongly favors the formation of aurone. Based on studies by Tremblay et al., ${ }^{20}$ we established a reliable, high-yielding and scalable linear route (Scheme 2) where acetophenones 3a and 3b served as starting materials (see the Supporting Information).

Rubottom oxidation and formation of the $\alpha$-hydroxyacetophenones 4, followed by double esterification with various 4substituted benzoyl chlorides, furnished precursors 5 that are

required for the Baker-Venkataraman rearrangement, consistently in excellent yields. In the presence of LiHMDS as a base, the anionic rearrangement led to the phenol 6. Next, a ring-closing condensation reaction led to the formation of flavonol esters 7. We found that elevated temperatures were required for substrates with chlorine or bromine substitution at C4', while complete conversion was already observed at room temperature (rt) for substrates that bear a methoxy or fluorine
substituent at this position. Subsequent saponification with sodium hydroxide gave the corresponding flavonols $\mathbf{8 a} \mathbf{- b c}$ in excellent yields. ${ }^{33}$

As mentioned before, these harsh acidic/basic reaction conditions were accompanied by several limitations. Incorporation of acid-labile protecting groups like MOM on the phenol functionality, as well as flavonols with sensitive structural modifications on the B-ring such as the pyridine
ring as well as electron-withdrawing groups such as 4nitrobenzene, is not feasible.
With the flavonols in hand, using methyl cinnamate, the synthesis proceeded with a UV light-mediated [3+2]-cycloaddition, followed by a ketol shift and finally diastereoselective reduction of the ketone according to the protocol of Rizzacassa et al. ${ }^{34}$ Methyl rocaglates $\mathbf{9 a - b c}$ were obtained in good yields. In the cases where a benzyloxy group was installed at C6, we were able to convert it to the corresponding methoxy ethers 11ba-bc via deprotection with $\mathrm{H}_{2}, \mathrm{Pd} / \mathrm{C}$ and methylation with trimethylsilyldiazomethane. ${ }^{20}$

Flavonol Synthesis Based on Algar-Flynn-Oyama-da-Type Reactions. Next, we turned our attention toward the modification of the C6 and C8 positions of rocaglates. As mentioned above, the AFO synthesis is a promising approach for the synthesis of flavonols that possess an electronwithdrawing substituent at C5 and C7 (corresponding to C6 and C 8 in the corresponding rocaglate) and an electronwithdrawing substituent at $\mathrm{C} 4^{\prime}$. Accordingly, we prepared a series of new halogenated rocaglates via the route depicted in Scheme 3. The acetophenones $3 \mathbf{c}-\mathbf{i}$ and 3 n were prepared from their respective 3,5 -substituted phenols by acetylation followed by Fries rearrangement, whereas $\mathbf{3 j}-\mathbf{m}$ were synthesized from their respective 3,5-dimethoxy halobenzenes by acylation and mono-demethylation (see Supporting Information).
According to a procedure by Sale et al., ${ }^{35}$ the acetophenones could be easily converted into chalcones $\mathbf{1 2 c} \mathbf{c}-\mathbf{n}$ in the presence of sodium ethoxide as a base. The subsequent AFO reaction using a mixture of NaOH and $\mathrm{H}_{2} \mathrm{O}_{2}$ gave the desired flavonols $\mathbf{8 c} \mathbf{c} \mathbf{n}$ in acceptable yields. Remarkably, this protocol also allowed the synthesis of flavonols $8 \mathbf{d b}$ and $8 \mathbf{n b}$ bearing electron-withdrawing substituents at the C 4 ' position. However, in these cases, significant proportions of corresponding aurones (see Scheme 1) were also formed. Analogous to flavonols 8a-bc prepared via the Baker-Venkataraman route, compounds $8 \mathbf{c}-\mathbf{n}$ were converted to rocaglate derivatives $9 \mathrm{c}-$ n using the established sequence. With the exception of the $4^{\prime}$ bromo rocaglates $\mathbf{9 d b}$ and $\mathbf{9 n b}$, yields of about $50 \%$ over three steps were obtained for the major endo-diastereomer.

Conversion of Rocaglate Methyl Esters to the Corresponding Amides. Starting from the new rocaglate methyl esters, selected members of this library were converted into amides (Scheme 4). It was previously demonstrated that the incorporation of both an $\mathrm{N}, \mathrm{N}$-dimethylamide and an N methoxyamide group can result in significantly improved antiviral activity. ${ }^{14,}$

Biological Studies. In total, we prepared 33 rocaglates as racemic mixtures via two different routes, with 30 of the derivatives containing one or more halogen atoms. Since it is known from previous work that the presence of a benzyloxy group at position 6 leads to decreased translational inhibition, ${ }^{21}$ compounds $9 \mathbf{b a}, \mathbf{9 b b}$ and $\mathbf{9 b c}$ were excluded from the study of antiviral activity. In addition to the resynthesized ( $\pm$ )-rocaglamide (rac-1b), ( $\pm$ )-CR-31-B (rac1c) and ( $\pm$ )-methylrocaglate (11bc), commercial ( - -)-silvestrol (2a) also served as a reference compound.
Hepatitis E viruses are characterized by a highly structured $5^{\prime}$ untranslated region ( $5^{\prime}$ UTR) and rely on cap-dependent translation for their efficient replication. ${ }^{36}$ Herein, we assessed structure-activity relationships of our new halogenated rocaglates and their potential as antiviral agents against HEV replication by transfecting hepatoma cells (HepG2) with the

0.15 to 1000 nM (Figure 3A,B). Luciferase activity and MTT assays were conducted to measure HEV RNA replication and cell viability, respectively. The obtained $\mathrm{EC}_{50}, \mathrm{EC}_{90}, \mathrm{CC}_{50}$ and selectivity index (SI) values are summarized in Figure 3C and Table 1.

In accordance with previous findings for non-halogenated compounds, ${ }^{14,23}$ an example of chlorinated C2-methyl ester 9a $\left(\mathrm{EC}_{90}=105.4 \mathrm{nM}\right)$ showed to be inferior in potency compared to its corresponding dimethylamide 14aa ( $\mathrm{EC}_{90}=101.6 \mathrm{nM}$ ) and its methoxyamide $\mathbf{1 4 a b}\left(\mathrm{EC}_{90}=18.2 \mathrm{nM}\right)$. To further support this outcome, the same series of derivatives with

fluorine instead of chlorine were tested. The result proved to be similar, with methoxyamide as the most potent member (14bab, $\mathrm{EC}_{90}=338.2 \mathrm{nM}$ ) compared to its dimethylamide 14baa $\left(\mathrm{EC}_{90}=828.8 \mathrm{nM}\right)$ and ester 11ba $\left(\mathrm{EC}_{90}>1000 \mathrm{nM}\right)$ ( $\mathrm{X}=\mathrm{NHOMe}>\mathrm{NMe}_{2}>\mathrm{OMe}$ ), respectively.
The observed improvement in $\mathrm{EC}_{90}$ values for amides may be attributed by the fact that carbonyl groups of the amide serve as better hydrogen bond donors to Gln 195 of eIF4A compared to methyl esters. ${ }^{17,18}$ Notably, enhanced inhibition of HEV replication was observed in the $\mathrm{C} 4^{\prime}$-bromo methyl ester 11bb ( $\mathrm{EC}_{90}=91.3 \mathrm{nM}$ ) compared to $\mathrm{C}^{\prime}$-chlorine 9a $\left(\mathrm{EC}_{90}=105.4 \mathrm{nM}\right)$ and $\mathrm{C}^{\prime}$-fluorine methyl ester 11ba $\left(\mathrm{EC}_{90}\right.$ $>1000 \mathrm{nM}$ ). Moreover, 9a and amide derivatives 14aa ( $\mathrm{EC}_{90}$ $=101.6 \mathrm{nM})$ and $\mathbf{1 4 a b}\left(\mathrm{EC}_{90}=18.2 \mathrm{nM}\right)$ displayed superior HEV inhibition compared to $\mathrm{C}^{\prime}$-methoxy substituents (rac$\mathbf{1 b}, r a c-1 c$ and 11bc). In contrast, fluorine functionalization in 11ba, 14baa and 14bab at position $\mathrm{C} 4^{\prime}$ resulted in decreased activity and cytotoxicity for methyl esters, $N$-dimethylamides and N -methoxyamides relative to $\mathrm{C}^{\prime}$ '-methoxy derivatives (compare 14bab $\left[\mathrm{EC}_{90}=338.2 \mathrm{nM} ; \mathrm{CC}_{50}=142.9 \mathrm{nM}\right]$ with rac-1c $\left[\mathrm{EC}_{90}=27.3 \mathrm{nM}, \mathrm{CC}_{50}=14.3 \mathrm{nM}\right]$, 14baa $\left[\mathrm{EC}_{90}=\right.$ $828.8 \mathrm{nM}, \mathrm{CC}_{50}=296.9 \mathrm{nM}$ ] with rac-1b $\left[\mathrm{EC}_{90}=201.3 \mathrm{nM}\right.$;
$\left.\mathrm{CC}_{50}=44.5 \mathrm{nM}\right]$ and 11ba $\left[\mathrm{EC}_{90}>1000 \mathrm{nM} ; \mathrm{CC}_{50}=421.4\right.$ nM ] with 11bc $\left[\mathrm{EC}_{90}=187.8 \mathrm{nM} ; \mathrm{CC}_{50}=65.3 \mathrm{nM}\right]$ ). These observations corresponded to the $\mathrm{EC}_{90}$ trends $\mathrm{Br}>\mathrm{Cl}>\mathrm{OMe}$ $>\mathrm{F}$ and $\mathrm{Cl}>\mathrm{OMe}>\mathrm{F}$ for methyl esters and carbonyl amides, respectively. To further elucidate the influence of halogen functionalization, we examined halogenated rocaglates substituted with $\mathrm{Br}, \mathrm{Cl}$ and F at positions 6 and 8 , or both, concerning their antiviral activity against HEV replication. The C8-bromo methyl ester $91\left(\mathrm{EC}_{90}=304.7 \mathrm{nM}\right)$ displayed marginally reduced activity compared to compound $9 \mathbf{e}\left(\mathrm{EC}_{90}\right.$ $=282.4 \mathrm{nM})$ (C8, C6-bromine substitution). Conversely, the introduction of a bromine atom solely at position C6 in 9 m $\left(\mathrm{EC}_{90}=30.6 \mathrm{nM} ; \mathrm{CC}_{50}=13.8 \mathrm{nM}\right)$ significantly enhanced both activity and cytotoxicity. A similar trend was observed for chlorine-substituted derivatives (compare 9j $\left[\mathrm{EC}_{90}=393.5\right.$ $\mathrm{nM}]$ with $9 \mathrm{da}\left[\mathrm{EC}_{90}=725.3 \mathrm{nM}\right]$ and $9 \mathrm{k}\left[\mathrm{EC}_{90}=45.5 \mathrm{nM}\right]$ ). However, C6- and C8-bromine substitutions generally produced more active compounds than their C6- and C8chlorine counterparts. Also, addition of a bromine atom (position C4) to an already halogenated derivative enhanced activity (compare 9na $\left[\mathrm{EC}_{90}=873.3 \mathrm{nM}\right]$ with $9 \mathrm{nb}\left[\mathrm{EC}_{90}=\right.$

${ }^{a}$ Designations of $\mathrm{R}^{1}-\mathrm{R}^{3}$ and X Are Presented in Figure 2. SI values represent mean SI values calculated from three biological replicates and therefore do not necessarily represent the ratio between $\mathrm{EC}_{50}$ and $\mathrm{CC}_{50}$ values listed in the table.
$298.0 \mathrm{nM}]$ or $9 \mathrm{da}\left[\mathrm{EC}_{90}=725.3 \mathrm{nM}\right]$ with $9 \mathrm{db}\left[\mathrm{EC}_{90}=123.9\right.$ $\mathrm{nM}]$ ).

Fluorine functionalization at position C 8 in carbonyl amides 14ha $\left(\mathrm{EC}_{90}=758.7 \mathrm{nM}\right)$ and $\mathbf{1 4 h b}\left(\mathrm{EC}_{90}=69.8 \mathrm{nM}\right)$ led to reduced activity compared to non-halogenated amides rac-1b and rac-1c. Intriguingly, the introduction of a fluorine moiety at position C 6 in $9 \mathrm{c}\left(\mathrm{EC}_{90}>1000 \mathrm{nM}\right)$ and $9 \mathrm{i}\left(\mathrm{EC}_{90}>1000\right.$ nM ) completely diminished antiviral activity in hepatoma cells.

Collectively, these findings demonstrate that bromine functionalization yielded the most significant improvement of activities when substituted at position $\mathrm{C} 6\left(\mathrm{C} 6>\mathrm{C} 4^{\prime}>\mathrm{C} 8\right)$, while chlorine substitutions led to the most potent increase in activity for position $\mathrm{C} 4^{\prime}\left(\mathrm{C}^{\prime}>\mathrm{C} 8\right)$. Conversely, fluorine functionalization at $\mathrm{C} 4^{\prime}$ and C 8 resulted in reduced antiviral activity and cytotoxicity and entirely abrogated activity when introduced at the C 6 position ( $\mathrm{C} 8>\mathrm{C} 4^{\prime}>\mathrm{C} 6$ ). Based on calculated SI values, two additional trends were observed. First, substitutions on ring A (position C6 and C8) tend to result in improved SI values compared to C 4 ' or C 2 substitutions. Also, derivatives with improved activity were observed to have better SI values than less potent derivatives.
Based on selectivity indices calculated for 48-h treated compounds, we identified 9 m and 9 da as the most promising
rocaglates in our investigation (Figure 3A). Consequently, we evaluated the antiviral efficacy of 9da and 9 m against CHIKV, RVF and SARS-CoV-2. Derivative 9 k and $\mathbf{1 4 m}$ were not included, due to high structural similarity of 9 k to 9 m and high toxicity observed for $\mathbf{1 4 m}$ at 48 h . Therefore, we also selected derivative $\mathbf{1 4 f}$ for further analysis. The C6, C8-chlorofunctionalized methyl ester 9da proved to be the least active derivative for all tested viruses (Figure 4A-C, Table 2). $N$ methoxyamide $\mathbf{1 4 f}$ exhibited less activity than the C6-bromofunctionalized 9 m for Chikungunya virus (CHIKV ) [ $\mathrm{EC}_{90}=$ 20.2 nM vs $\mathrm{EC}_{90}=9.8 \mathrm{nM}$ ], Rift Valley fever virus (RVFV) $\left[\mathrm{EC}_{90}=113.2 \mathrm{nM}\right.$ vs $\mathrm{EC}_{90}=53.2 \mathrm{nM}$ ] and SARS-CoV-2 $\left[\mathrm{EC}_{90}=339.9 \mathrm{nM}\right.$ vs $\mathrm{EC}_{90}=80.0 \mathrm{nM}$ ], while $\mathbf{1 4 f}$ and 9 m showed similar activity against HEV. Finally, we evaluated the influence of the cell density on the antiviral activity of exemplified for 9 m by comparing the standard protocol cell density to that of a confluent monolayer. As depicted in Figure S1, cell viability improved when cell density was higher. However, at the same time the antiviral response of 9 m decreased, which is likely due to the greater number of cells replicating the HEV genome, necessitating a higher dose of the drug to achieve the same reduction of replication (Figure S1).

Figure 4. Pan-antiviral inhibition of HEV, Chikungunya virus (CHIKV), Rift Valley fever virus (RVFV) and SARS-CoV-2 replication by $\mathbf{9 m}$, 9 da and 14f. A) HEV subgenomic replicon HEVp6-Gluc was electroporated into HepG2 cells. Cells were treated with 9m, 9da and 14f at concentrations ranging from 0.15 nM to 1000 nM for 24 and 48 h . Depicted are nonlinear fit response curves representative of three biological replicates for HEVp6-Gluc (dark blue lines), and cell viability was monitored by MTT assay (gray lines). Error bars indicate standard deviation, $n=$ 3. B) Huh-7 cells were treated with different concentrations ( 0.15 nM to 1000 nM ) of $\mathbf{9 m}$, $\mathbf{9} \mathbf{d a}$ and $\mathbf{1 4 f}$ and infected at a MOI of 2.5 with infectious clone CHIKV LR2006-OPY1 expressing GFP under the control of a subgenomic promotor. GFP expression as measure of infection (left panel) and cell viability (right panel) were measured by live cell imaging and MTT assay, respectively. C) Vero-E6 cells were infected with SARS-CoV-2 or RVF strain MP-12 at a multiplicity of infection (MOI) of 0.1 . Supernatants were collected at 24 h post infection (hpi) or 48 hpi and subjected to RT-qPCR analysis as measure of infection (left and middle panel). Cell viability was determined by MTT assay (right panel).

## - CONCLUSION

One of the most promising targets for inhibition of viral protein synthesis is the eukaryotic initiation factor (eIF) 4 F complex (comprised of eIF4A, 4E and 4G). Due to a highly structured viral $5^{\prime}$-untranslated region ( $5^{\prime}$ UTR), a large number of RNA viruses require the DEAD-box RNA helicase activity of eIF4A to unwind the viral genome and to allow for the recruitment and scanning of the $43 S$-pre-initiation complexes (43S-PIC) during translation initiation. ${ }^{37}$ Intriguingly, several previous studies have reported that inhibition of the eIF4A complex by rocaglates could prevent replication of different RNA viruses in vitro and in vivo. ${ }^{38}$ In this study, a library of 27 halogenated derivatives of rocaglamide was synthesized via two different synthetic routes. Subsequent biological evaluation of the modified rocaglate derivatives revealed an potential antiviral effect on hepatitis E (HEV) and moderate antiviral activities against Chikungunya (CHIKV), Rift Valley river virus (RVFV) and SARS-CoV-2 viruses. In addition, the compounds exerted some cytostatic effects, which was reflected by the low to moderate SI values. The biological
tests revealed various structure-activity findings about the rocaglates, especially with regard to positions $4^{\prime}, 6$ and 8 (Figure $5 \mathrm{~A}-\mathrm{C}$ ). For the $4^{\prime}$ position, an increase in activity of F $<\mathrm{OMe}<\mathrm{Cl}<\mathrm{Br}$ was found. The bromine derivative is thus more active than the rocaglate with the methoxy group found in the natural products. The fluorine derivative, on the other hand, exerts hardly any antiviral activity. For the 6 position the trend is as follows. Here fluorine leads to complete loss of antiviral activity followed by $\mathrm{OMe}<\mathrm{Cl}<\mathrm{Br}$. Finally, the replacement of the methoxy group in position 8 gave the following relationship: $\mathrm{Br} \sim \mathrm{Cl}<\mathrm{F}<\mathrm{OMe}$. Replacing the methoxy groups at positions 6 and 8 with two identical substituents results in the following picture: $\mathrm{F} \ll \mathrm{MeO} \sim \mathrm{Br}<$ Cl . The antiviral activity of the dichloro derivative 9 da is further enhanced when the methoxy group at $\mathrm{C} 4^{\prime}$ is replaced by bromine, as in rocaglate $\mathbf{9 d b}$. Finally, it was found that the best halogen combination at positions 6 and 8 is bromine at C6 and chlorine at C8 in rocaglate derivative 9 f .

It is remarkable that the medicinal-chemically relevant halogen fluorine shows a negative influence on the antiviral

properties of rocaglates, at least in particular at positions $4^{\prime}$ and 6 , less so at position 8 .
Another trend worth mentioning is the fact that substitutions at the A ring (C6, C8) lead overall to better SI values in terms of activity than modifications at $\mathrm{C} 4^{\prime}$ or at C 2 (ester to amide). In general, more antiviral active derivatives show on average a better SI value than derivatives with lower activity.

This study contributes to the elucidation of new structureactivity relationship for a series of antiviral compounds targeting a panel of human pathogenic viruses. We identified compounds 9 m and $\mathbf{1 4 f}$, which are all more potent than the
natural product $( \pm)$-rocaglamide (rac-1b) and similarly potent as (-)-silvestrol (2a), as potential candidates for further studies. The cytotoxicity of these compounds is comparatively low warranting further explorations. Finally, one may speculate about the special effect of halogen substitution presented in this work. The report by Iwasaki and co-workers ${ }^{10}$ on the resolved structure of the human complex composed of eIF4A1, AMPPNP, rocaglamide $\mathbf{1 b}$ and polypurine RNA provides insight into this matter, because ring A in $\mathbf{1 b}$, that we modified with halogen substituents, is directed toward the polypurine RNA, specifically the adenine base of A7 and guanine base of G8. Halogen bonding, ${ }^{39}$ which resembles the electron density donation-based weak interaction of halogens with Lewis bases, including nucleobases, ${ }^{40}$ may provide a rationale for the observations reported here. A telling example is clindamycin, a halogenated ribosome binder that binds into the 50 S subunit. ${ }^{41}$ It contains one chlorine atom that is directed toward the sugar edge of guanosine and forms an interaction with the guanine nitrogen atom. ${ }^{40}$

Particularly, the introduction of bromine at position 6 in ring A leads to improved antiviral properties and this may be associated with halogen bonding toward the adenine base of A7 and guanine base at G8 (Figure 5D). In the future, structural biology studies should provide a deeper understanding of the halogen effect observed here.

## EXPERIMENTAL SECTION

Chemical Synthesis: General Methods. All experiments involving water-sensitive compounds were carried out in dried glassware under argon or nitrogen. Anhydrous solvents ( MeCN , $\mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{Et}_{2} \mathrm{O}, \mathrm{PhMe}$ ) were obtained from a M. Braun MB solvent purification system or commercial solvents were used as supplied. Petroleum ether and dichloromethane were distilled before application and triethylamine was dried over KOH and distilled as well. Commercial reagents were used as supplied. Thin-layer chromatography (TLC) was performed on aluminum-backed plates precoated ( 0.25 mm ) with silica gel 60 F 254 with a suitable solvent system and was visualized using UV fluorescence and/or developed with $\mathrm{KMnO}_{4}$, anisaldehyde or vanillin stain followed by brief heating. For column chromatography, silica gel ( $35-70 \mu \mathrm{~m}$ ) was used. Alternatively, a Biotage SP purification system was used. Biotage silica cartridges were used as supplied. All compounds are $>95 \%$ pure. The purity of tested compounds was determined by analytical liquid
chromatography of solutions of the compounds in DMSO- $d_{6}$. Waters Alliance 2695 LC with a Waters Acquity 2996 photodiode array detector equipped with a Varian Polaris C18-A column $(5.0 \mu \mathrm{~m}, 50$ $\mathrm{mm} \times 2.0 \mathrm{~mm})$. The mobile phases were (A) $0.1 \%$ formic acid in water and (B) $0.1 \%$ formic acid in acetonitrile. After injection the gradient holds were at $\mathrm{A} / \mathrm{B}(90 \% / 10 \%)$ for 1.00 min followed by a gradient to $\mathrm{A} / \mathrm{B}(0 \% / 100 \%)$ over 1.75 min , a 0.05 min flush at $0 \% /$ $100 \%(\mathrm{~A} / \mathrm{B})$ and a 1.20 min re-equilibration at $\mathrm{A} / \mathrm{B}(90 \% / 10 \%)$ at a flow rate of $0.8 \mathrm{~mL} / \mathrm{min}$ and a column temperature of $45{ }^{\circ} \mathrm{C} .{ }^{1} \mathrm{H}$ NMR spectra are represented as follows: chemical shift, multiplicity (s $=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{q} \mathrm{i}=$ quintet, $\mathrm{sx}=$ sextet, $\mathrm{sp}=$ septet, $\mathrm{bs}=$ broad singlet, $\mathrm{m}=$ multiplet $)$, coupling constant $(J)$ in hertz (Hz), integration and assignment. ${ }^{13} \mathrm{C}$ NMR spectra are represented as follows: chemical shift, substitution ( $\mathrm{p}=$ primary, $\mathrm{s}=$ secondary, $\mathrm{t}=$ tertiary, $\mathrm{q}=$ quaternary $)$ and assignment. ${ }^{19} \mathrm{~F}$ NMR spectra are represented as follows: multiplicity ( $\mathrm{s}=$ singlet, $\mathrm{d}=$ doublet, $\mathrm{t}=$ triplet, $\mathrm{q}=$ quartet, $\mathrm{qi}=$ quintet, $\mathrm{sx}=$ sextet, $\mathrm{sp}=$ septet, $\mathrm{bs}=$ broad singlet, $\mathrm{m}=$ multiplet), coupling constant $(J)$ in hertz $(\mathrm{Hz})$, integration and assignment. The numbering of the carbon and hydrogen atoms of the rocaglates synthesized follows the IUPAC nomenclature. A list of all rocaglates including the numbering of the carbon and hydrogen atoms is provided in the Supporting Information. ${ }^{1} \mathrm{H}$ NMR, ${ }^{13} \mathrm{C}$ NMR and ${ }^{19} \mathrm{~F}$ NMR spectra were recorded using a Bruker Ultrashield 500 MHz with Avance-III HD console, a Bruker Ascend 400 MHz with Avance-III console, a Bruker Ascend 400 MHz with Avance-III HD console, a Bruker Ultrashield 400 MHz with Avance-I console and a Bruker Ascend 600 MHz with Avance Neo console. High-resolution mass spectrometry (HRMS) data was measured with a Micromass LCT with lockspray source. The injection proceeded in loop-mode with a HPLC system by Waters (Alliance 2695). Alternatively, mass spectra were recorded with an Acquity-UPLC system by Waters in combination with a Q-Tof Premier mass spectrometer by Waters in lockspray mode. The ionization happened by electrospray ionization (ESI) or by chemical ionization at atmospheric pressure (APCI). The calculated and found mass are reported. GC/MS analyses were carried out with an HP 6890 chromatograph with KAS 4, coupled to an HP 5973 quadrupole mass selective detector. Samples were analyzed on an Optima 5 column (poly( $5 \%$ phenyl-95\% methylsiloxane), $30 \mathrm{~m} \times 0.32 \mathrm{~mm}$ i.d. $\times$ film thickness $0.25 \mu \mathrm{~m}$ ). Carrier gas, He; injector temp., 60 to 300 ${ }^{\circ} \mathrm{C}$ at $12{ }^{\circ} \mathrm{C} / \mathrm{min}$, splitless; temp. program: $50^{\circ} \mathrm{C}$ (isothermal 1 min ) to $300^{\circ} \mathrm{C}$, at $20^{\circ} \mathrm{C} / \mathrm{min}$ and held isothermal for 6 min at $300^{\circ} \mathrm{C}$; ion source: EI, ionization energy, 70 eV ; electron mass spectra were acquired over the mass range of $40-500 \mathrm{amu}$.

Synthesis of $( \pm)$-Methyl $(1 R, 2 R, 3 S, 3 \mathrm{a} R, 8 \mathrm{bS})$-3a-(4-chloro-phenyl)-1,8b-dihydroxy-6,8-dimethoxy-3-phenyl-2,3,3a,8b-tetrahydro-1H-cyclopenta[b]benzofuran-2-carboxylate (9a).

2-Hydroxy-1-(2-hydroxy-4,6-dimethoxyphenyl)ethan-1-one (4a). To a solution of 1-(2-hydroxy-4,6-dimethoxyphenyl)ethan-1-one (3a +) $\left(3.52 \mathrm{~g}, 17.9 \mathrm{mmol}, 1.00\right.$ equiv) in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(36 \mathrm{~mL})$ were added freshly distilled $\mathrm{Et}_{3} \mathrm{~N}(9.3 \mathrm{~mL}, 47.9 \mathrm{mmol}, 2.67$ equiv) and TBSOTf ( $9.5 \mathrm{~mL}, 41.3 \mathrm{mmol}, 2.30$ equiv) at $0{ }^{\circ} \mathrm{C}$ and stirred at the same temperature for 4 h . The reaction was terminated by the addition saturated aqueous $\mathrm{NaHCO}_{3}(50 \mathrm{~mL})$ and warmed up to rt. The layers were separated and the aqueous layers were extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times 50 \mathrm{~mL})$. The collected organic layers were washed with brine, dried over $\mathrm{MgSO}_{4}$, filtered and concentrated in vacuo. The crude/biphasic solution was diluted with $\mathrm{Et}_{2} \mathrm{O}$, washed with a saturated aqueous $\mathrm{NH}_{4} \mathrm{Cl}$ solution, dried over $\mathrm{MgSO}_{4}$, filtered and concentrated in vacuo. The solvent residue was removed under high vacuum and the crude TBS-enol ether as thick red syrup was used directly for the next step. A suspension of $\mathrm{NaHCO}_{3}(3.21 \mathrm{~g}, 38.2$
mmol, 2.50 equiv) and $m \mathrm{CPBA}(77 \mathrm{wt} \%, 6.04 \mathrm{~g}, 35.0 \mathrm{mmol}, 1.60$ equiv) in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(44 \mathrm{~mL})$ was prepared and stirred at rt for 30 min. A solution of crude TBS-enol ether $(6.50 \mathrm{~g})$ in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(23$ mL ) was then added to the $m \mathrm{CPBA}$ suspension at $0^{\circ} \mathrm{C}$ and stirred for 30 min . The reaction mixture was warmed up to rt and stirred for 2 h . The reaction was terminated by dilution with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and washed extensively with $\mathrm{NaHCO}_{3}$ (sat., aq.) to remove the $m \mathrm{CPBA}$ residue. The organic layers were washed with water, NaCl (sat., aq.), dried over $\mathrm{MgSO}_{4}$, filtered and concentrated in vacuo. The thick red syrup crude was used for the next reaction without further purification. To the epoxide crude $(6.69 \mathrm{~g})$ in $\mathrm{THF} / \mathrm{H}_{2} \mathrm{O}(10: 1,66 \mathrm{~mL})$ was added $p \mathrm{TsOH} \cdot \mathrm{H}_{2} \mathrm{O}(0.29 \mathrm{mg}, 1.5 \mathrm{mmol}, 0.10$ equiv) and stirred under refluxing conditions for 6 h . The reaction was cooled down to rt and extracted with EtOAc , washed with $\mathrm{NaHCO}_{3}$ (sat., aq.), water, NaCl (sat., aq.), dried over $\mathrm{MgSO}_{4}$, filtered and concentrated in vacuo. The crude extract was stirred under refluxing conditions in EtOH for 1 h and slowly precipitated overnight at rt. The suspension was filtered and washed with cold EtOH to afford $\mathbf{4 a}$ as a pale-orange solid (1.09 g, $5.13 \mathrm{mmol}, 60 \%$ over three steps). $R_{\mathrm{f}}=0.42$ (petroleum ether/ EtOAc 1:1); ${ }^{1} \mathbf{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{MHz}\right): \delta[\mathrm{ppm}] 13.22$ ( $\mathrm{s}, 1 \mathrm{H}$, $\mathrm{OH}), 6.11(\mathrm{~d}, J=2.3 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{ArH}), 5.94(\mathrm{~d}, J=2.3 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{ArH})$, $4.71\left(\mathrm{~s}, 2 \mathrm{H}, \mathrm{CH}_{2} \mathrm{OH}\right), 3.87\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right), 3.84\left(\mathrm{~s}, 3 \mathrm{H}, \mathrm{OCH}_{3}\right) ;{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}, 100 \mathrm{MHz}\right): \delta[\mathrm{ppm}] 201.9(\mathrm{q}, \mathrm{C}=\mathrm{O}), 167.3(\mathrm{q}, \mathrm{ArC})$, 167.1 ( $q, \operatorname{ArC}$ ), $163.32(q, \operatorname{ArC}), 93.8(\mathrm{t}, \operatorname{ArCH}), 91.0(\mathrm{t}, \mathrm{ArCH}), 68.9$ $\left(\mathrm{s}, \mathrm{CH}_{2} \mathrm{OH}\right), 55.73\left(\mathrm{p}, \mathrm{OCH}_{3}\right), 55.71\left(\mathrm{p}, \mathrm{OCH}_{3}\right)$. The analytical data are consistent with those reported in the literature. ${ }^{21}$

2-(2-((4-Chlorobenzoyl)oxy)-4,6-dimethoxyphenyl)-2-oxo-ethyl 4-chlorobenzoate (5a). To a solution of alcohol $4 \mathrm{a}(1.09 \mathrm{~g}, 5.16$ mmol, 1.00 equiv) in dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}(14 \mathrm{~mL})$ were added DMAP ( 0.03 $\mathrm{mg}, 0.26 \mathrm{mmol}, 0.05$ equiv) and freshly distilled triethylamine ( 2.2 $\mathrm{mL}, 15.5 \mathrm{mmol}, 3.00$ equiv) and cooled down to $0^{\circ} \mathrm{C}$. To the cold suspension was added 4-chlorobenzoyl chloride ( $0.36 \mathrm{~mL}, 2.69 \mathrm{mmol}$, 2.00 equiv) and warmed up to rt. The orange suspension was stirred at rt for 3 h , before the reaction was terminated by the addition of HCl solution ( $1 \mathrm{M}, 15 \mathrm{~mL}$ ). The layers were separated and the aqueous layers were extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The reaction was terminated by the addition $\mathrm{NaHCO}_{3}$ solution (sat., aq.) and was allowed to warm to rt. The phases were separated and the aqueous phase was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times)$. The combined organic phases were dried over $\mathrm{MgSO}_{4}$, filtered and concentrated under reduced pressure. The yielding two-phasic mixture of the product and triethylammonium triflate was diluted with $\mathrm{Et}_{2} \mathrm{O}$ and $\mathrm{NH}_{4} \mathrm{Cl}$ solution (sat., aq.) and the phases were separated. The aqueous phase was extracted with $\mathrm{Et}_{2} \mathrm{O}(100 \mathrm{~mL}, 3 \times)$. The organic phases were combined, dried over $\mathrm{MgSO}_{4}$, filtered and concentrated under reduced pressure. The TBS-enol ether was collected as a salmon-colored solid ( 31.8 g ) and dissolved in $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ $(60.0 \mathrm{~mL})$ and added to a suspension of $m \mathrm{CPBA}(77 \mathrm{wt} \%, 21.4 \mathrm{~g}$, 86.8 mmol, 1.40 equiv) and $\mathrm{NaHCO}_{3}(11.2 \mathrm{~g}, 133 \mathrm{mmol}, 2.15$ equiv) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(240 \mathrm{~mL})$ at $0{ }^{\circ} \mathrm{C}$. Methyl cinnamate ( $3.20 \mathrm{~g}, 19.7 \mathrm{mmol}, 14.2$ equiv) was added to a solution of flavonol $\mathbf{8 b b}(629 \mathrm{mg}, 1.39 \mathrm{mmol}, 1.00$ equiv) in dry chloroform ( 28.3 mL ) and freshly distilled $2,2,2$-trifluoroethanol ( 11.3 mL ). The reaction mixture was degassed for 30 min , then cooled to $-5^{\circ} \mathrm{C}$ and irradiated with UV light ( $\lambda_{\max }=365 \mathrm{~nm}$ ) until it no longer fluoresced greenish ( 24 h ). Subsequently, the solvent was removed under reduced pressure. The remaining amount of methyl cinnamate was then removed by column chromatography (petroleum ether/EtOAc 5.5:1 $\rightarrow 1: 1$ ). The desired cycloadduct was obtained as a mixture of isomers as a yellowish foam $(629 \mathrm{mg})$. Without any further purification the product of the first step ( $629 \mathrm{mg}, 1.02 \mathrm{mmol}, 1.00$ equiv) was dissolved in $\mathrm{MeOH}(40.9 \mathrm{~mL}$ ). Then NaOMe solution ( $25 \mathrm{wt} \%$ in $\mathrm{MeOH}, 799 \mu \mathrm{~L}, 3.37 \mathrm{mmol}, 3.30$ equiv) was added and the mixture was heated under refluxing conditions for 1 h . Subsequently, the reaction was terminated by the addition of $\mathrm{NH}_{4} \mathrm{Cl}$ solution (sat., aq.). The phases were separated and the aqueous phase was extracted with EtOAc $(3 \times)$. The organic phases were combined, dried over $\mathrm{MgSO}_{4}$, filtered and the solvent was removed under reduced pressure. The desired keto ester was obtained as a mixture of isomers as a yellow, glassy foam ( 629 mg ) and used directly for the next step. A mixture of $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{~N}(\mathrm{OAc})_{3} \mathrm{BH}(1.73 \mathrm{~g}, 6.56 \mathrm{mmol}, 6.42$ equiv) and freshly distilled AcOH ( $612 \mu \mathrm{~L}, 10.6 \mathrm{mmol}, 10.4$ equiv) in $\mathrm{MeCN}(9.00 \mathrm{~mL}$ ) was stirred for 5 min at rt . Then, a solution of the product of the second step ( $629 \mathrm{mg}, 1.02 \mathrm{mmol}, 1.00$ equiv) in $\mathrm{MeCN}(6.00 \mathrm{~mL})$ was added. The mixture was protected from light and stirred for 19 h at rt . The reaction was then terminated by adding $\mathrm{NH}_{4} \mathrm{Cl}$ solution (sat., aq.) and sodium potassium tartrate solution (aq., 2.00 M ). The phases were separated and the aqueous layer was extracted with
$\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times)$. The combined organic layers were dried over $\mathrm{MgSO}_{4}$, filtered and concentrated under reduced pressure. Column chromatography (petroleum ether/EtOAc $5: 1 \rightarrow 1: 1$ ) was then performed to obtain the racemic endo-product $\mathbf{9 b b}$ as a pale-yellow solid ( $293 \mathrm{mg}, 483 \mu \mathrm{~mol}, 35 \%$ over three steps). $R_{\mathrm{f}}=0.52$ (petroleum ether/EtOAc 1:1); ${ }^{1} \mathbf{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{MHz}\right): \delta$ [ppm] 7.47-7.34 (m, 5H, H-3"', H-4"', H-5"', H-6"', H-7"'), 7.26 (d, J = 8.7 Hz, H-3', $\left.H-5^{\prime}\right), 7.08-7.05$ (m, 5H, H-2', H-6', H-3", H-4", H-5" ), 6.89-6.86 (m, 2H, H-2", H-6" ), 6.36 (d, $J=1.9 \mathrm{~Hz}, 1 \mathrm{H}, H-5$ ), 6.22 (d, $J=1.9$ $\mathrm{Hz}, 1 \mathrm{H}, H-7), 5.09\left(\mathrm{~s}, 2 \mathrm{H}, H-1^{\prime \prime \prime}\right), 5.01$ (dd, $\left.J=6.5,1.4 \mathrm{~Hz}, 1 \mathrm{H}, H-1\right)$, $4.35(\mathrm{~d}, J=14.2 \mathrm{~Hz}, 1 \mathrm{H}, H-3), 3.81(\mathrm{dd}, J=14.2,6.5 \mathrm{~Hz}, 1 \mathrm{H}, H-2)$, 3.86 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{O}-8$ ), 3.66 ( $\left.\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{O}-11\right), 3.59(\mathrm{~s}, 1 \mathrm{H}, \mathrm{OH}-8 \mathrm{~b})$, $1.85(\mathrm{~s}, 1 \mathrm{H}, \mathrm{OH}-1) ;{ }^{13} \mathrm{C}$ NMR $\left(\mathrm{CDCl}_{3}, 100 \mathrm{MHz}\right): \delta[\mathrm{ppm}] 170.5$ ( $q, C-11), 163.5$ (q, C-6), 160.8 ( $q, C-4 a), 157.1$ ( $q, C-8$ ), 136.6 ( $q$, C-2"'), 136.5 ( $q, C-1^{\prime \prime}$ ), 133.9 ( $\left.q, C-1^{\prime}\right), 130.4$ (t, C-3', C-5'), 129.6 (t, C-2', C-6'), 128.9 ( $\mathrm{t}, \mathrm{C}-4^{\prime \prime \prime}, C-6^{\prime \prime \prime}$ ), 128.4 ( $\mathrm{t}, \mathrm{C}-5^{\prime \prime \prime}$ ), 128.0 ( $\mathrm{t}, \mathrm{C}-3^{\prime \prime}, \mathrm{C}-$ $\left.5^{\prime \prime}\right), 127.8\left(\mathrm{t}, C-2^{\prime \prime}, C-6^{\prime \prime}\right), 127.7\left(\mathrm{t}, C-3^{\prime \prime \prime}, C-7^{\prime \prime \prime}\right), 126.9\left(\mathrm{t}, C-4^{\prime \prime}\right)$, 121.8 (q. 2-(4-(Benzyloxy)-2-methoxy-6-((4-methoxybenzoyl)oxy)phenyl)-2oxoethyl 4-methoxybenzoate (5bc). A solution of the $\alpha$-hydroxy ketone $\mathbf{4 b}\left(4.27 \mathrm{~g}, 14.8 \mathrm{mmol}, 1.00\right.$ equiv) in $\mathrm{CH}_{2} \mathrm{Cl}_{2}(40.0 \mathrm{~mL})$ was treated with 4 -DMAP ( $90.4 \mathrm{mg}, 740 \mu \mathrm{~mol}, 5 \mathrm{~mol} \%$ ) and triethylamine ( $6.19 \mathrm{~mL}, 44.4 \mathrm{mmol}, 3.00$ equiv). The mixture was cooled to $0^{\circ} \mathrm{C}$ and 4-methoxybenzoyl chloride ( $4.01 \mathrm{~mL}, 29.6 \mathrm{mmol}$, 2.00 equiv) was added and stirred at rt for 3 h . The solution was terminated by the addition of $\mathrm{HCl}\left(1.00 \mathrm{M}\right.$ in $\left.\mathrm{H}_{2} \mathrm{O}.\right)$ and the phases were separated. The aqueous phase was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(1 \mathrm{x})$. The combined organic phases were dried over $\mathrm{MgSO}_{4}$, filtered and concentrated under reduced pressure. The desired bisbenzoate 5bc was obtained as a yellow foam ( 8.24 g ) and was used directly for the next step. $R_{\mathrm{f}}=0.28$ (petroleum ether/EtOAc 2:1).

1-(4-(Benzyloxy)-2-hydroxy-6-methoxyphenyl)-3-(4-methoxy-phenyl)-1,3-dioxopropan-2-yl 4-methoxybenzoate (6bc). A solution of crude bisbenzoate $5 \mathbf{b c}(8.24 \mathrm{~g}, 14.8 \mathrm{mmol}, 1.00$ equiv $)$ in THF $(80.0 \mathrm{~mL})$ was cooled to $-20^{\circ} \mathrm{C}$ and treated with LiHMDS $(1.00 \mathrm{M}$ in THF, $44.4 \mathrm{~mL}, 44.4 \mathrm{mmol}, 3.00$ equiv). The mixture was stirred at $-20^{\circ} \mathrm{C}$ for 1 h . Then, the reaction was terminated by the addition of $\mathrm{NH}_{4} \mathrm{Cl}$ solution (sat., aq.) and warmed to rt. The aqueous phase was extracted with EtOAc ( $3 \times$ ) and the combined organic phases were dried over $\mathrm{MgSO}_{4}$, filtered and concentrated under reduced pressure. The desired phenol $\mathbf{6 b c}$ was obtained as a yellow foam ( 8.24 g ) and used directly for the next step. $R_{\mathrm{f}}=0.30$ (petroleum ether/EtOAc 2:1).

7-(Benzyloxy)-5-methoxy-2-(4-methoxyphenyl)-4-oxo-4H-chro-men-3-yl 4-methoxybenzoate (7bc). A suspension of crude phenol $\mathbf{6 b c}(8.24 \mathrm{~g}, 14.8 \mathrm{mmol}, 1.00$ equiv) in $\mathrm{AcOH}(170 \mathrm{~mL})$ was treated with $\mathrm{H}_{2} \mathrm{SO}_{4}$ ( $96 \mathrm{wt} \%, 4.11 \mathrm{~mL}, 74.0 \mathrm{mmol}, 5.00$ equiv) and stirred at rt for 15 h . The reaction mixture was poured into ice-cold $\mathrm{H}_{2} \mathrm{O}$ and stirred for 15 min . Thereby, a pale-pink precipitate was formed. The mixture was filtered on a Büchner funnel and the precipitate was washed with $\mathrm{H}_{2} \mathrm{O}$. The wet solid was suspended in a minimal amount of ethanol and heated to reflux for 1 h . The mixture was allowed to cool to rt, filtered on a Büchner funnel and washed with a small amount of cold ethanol. Methyl cinnamate ( $6.14 \mathrm{~g}, 37.9 \mathrm{mmol}, 14.2$ equiv) was added to a solution of flavonol $102(1.01 \mathrm{~g}, 2.67 \mathrm{mmol}, 1.00$ equiv) in dry chloroform ( 51.2 mL ) and freshly distilled 2,2,2-trifluoroethanol ( 22.0 mL ). The reaction mixture was degassed for 30 min , then cooled to $-5^{\circ} \mathrm{C}$ and irradiated with UV light ( $\lambda_{\text {max }}=365 \mathrm{~nm}$ ) until it no longer fluoresced greenish ( 20 h ). Subsequently, the solvent was removed under reduced pressure and the remaining amount of methyl cinnamate was removed by column chromatography (petroleum ether/EtOAc 4:1 $\rightarrow$ $1: 1$ ). The desired cycloadduct was obtained as a mixture of isomers as a yellowish foam ( 1.37 g ). Without any further purification the product of the first step ( $1.37 \mathrm{~g}, 2.41 \mathrm{mmol}, 1.00$ equiv) was dissolved in $\mathrm{MeOH}(80.0 \mathrm{~mL})$. Then, NaOMe solution ( $25 \mathrm{wt} \%$ in MeOH , $1.10 \mathrm{~mL}, 6.85 \mathrm{mmol}, 2.84$ equiv) was added and the mixture was heated under refluxing conditions for 1 h . Subsequently, the reaction was terminated by the addition of $\mathrm{NH}_{4} \mathrm{Cl}$ solution (sat., aq.). The phases were separated and the aqueous phase was extracted with EtOAc ( $3 \times$ ). The organic phases were combined, dried over $\mathrm{MgSO}_{4}$, filtered and concentrated under reduced pressure. The desired keto ester was obtained as a mixture of isomers as a yellow, glassy foam $(1.33 \mathrm{~g})$. About half of the product $(697 \mathrm{mg})$ was used for the next step without further purification. A mixture of $\left(\mathrm{CH}_{3}\right)_{4} \mathrm{~N}(\mathrm{OAc})_{3} \mathrm{BH}$ ( $2.08 \mathrm{~g}, 7.90 \mathrm{mmol}, 6.42$ equiv) and freshly distilled $\mathrm{AcOH}(732 \mu \mathrm{~L}$, $12.8 \mathrm{mmol}, 10.4$ equiv) in $\mathrm{MeCN}(32.0 \mathrm{~mL})$ was stirred for 5 min at rt . Then, a solution of the product of the second step $(697 \mathrm{mg}, 1.23$ mmol, 1.00 equiv) in $\mathrm{MeCN}(21.3 \mathrm{~mL})$ was added. The mixture was protected from light and stirred for 19 h at rt . The reaction was then terminated by adding $\mathrm{NH}_{4} \mathrm{Cl}$ solution (sat., aq.) and sodium potassium tartrate solution (aq., 2.00 M ). The phases were separated and the aqueous layer was extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \times)$. The combined organic layers were dried over $\mathrm{MgSO}_{4}$, filtered and concentrated under reduced pressure. Column chromatography (petroleum ether/EtOAc 3:2) was then performed to obtain the racemic endo-product 9bc as a pale-yellow solid ( $423 \mathrm{mg}, 744 \mu \mathrm{~mol}$, $56 \%$ yield over three steps). $R_{\mathrm{f}}=0.63$ (petroleum ether/EtOAc 1:2); ${ }^{1} \mathrm{H}$ NMR $\left(\mathrm{CDCl}_{3}, 400 \mathrm{MHz}\right): \delta[\mathrm{ppm}] 7.47-7.35\left(\mathrm{~m}, 5 \mathrm{H}, \mathrm{H}-3^{\prime \prime \prime}, \mathrm{H}-\right.$ $\left.4^{\prime \prime \prime}, H-5^{\prime \prime \prime}, H-6^{\prime \prime \prime}, H-7^{\prime \prime \prime}\right), 7.11\left(\mathrm{~d}, J=8.9 \mathrm{~Hz}, 2 \mathrm{H}, \mathrm{H}-2^{\prime}, H-6^{\prime}\right), 7.08-$ 7.05 (m, 3H, H-3", H-4", H-5"), 6.88-6.86 (m, 2H, H-2", H-6"), 6.68 (d, $\left.J=8.9 \mathrm{~Hz}, 2 \mathrm{H}, H-3^{\prime}, H-5^{\prime}\right), 6.36(\mathrm{~d}, J=1.9 \mathrm{~Hz}, 1 \mathrm{H}, H-5)$, 6.22 (d, $J=1.9 \mathrm{~Hz}, 1 \mathrm{H}, H-7$ ), 5.09 ( $\left.\mathrm{s}, 2 \mathrm{H}, H-1^{\prime \prime \prime}\right), 5.03$ (dd, $J=6.7$, $1.6 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{H}-1$ ), $4.31(\mathrm{~d}, J=14.2 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{H}-3), 3.90(\mathrm{dd}, J=14.4$, $6.5 \mathrm{~Hz}, 1 \mathrm{H}, \mathrm{H}-2$ ), 3.86 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{O}-8$ ), 3.71 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{O}-4^{\prime}$ ), 3.67 (br, $1 \mathrm{H}, \mathrm{OH}-8 \mathrm{~b}$ ), 3.65 ( $\mathrm{s}, 3 \mathrm{H}, \mathrm{CH}_{3} \mathrm{O}-11$ ), $1.77(\mathrm{~s}, 1 \mathrm{H}, \mathrm{OH}-1) ;{ }^{13} \mathrm{C}$ NMR ( $\left.\mathrm{CDCl}_{3}, 100 \mathrm{MHz}\right): \delta[\mathrm{ppm}] 170.7$ (q, C-11), 163.4 (q, C-6), 161.0 ( $q, C-4 \mathfrak{a}), 158.9$ ( $\left.q, C-4^{\prime}\right), 157.1(q, C-8), 137.0\left(q, C-1^{\prime \prime}\right)$, 136.6 (q, C-2"'), 129.1 (t, C-3', C-5'), 128.8 (t, C-4"', C-6"'), 128.3 (t, C-5"'), 128.0 ( $\mathrm{t}, \mathrm{C}-3^{\prime \prime}, \mathrm{C}-5^{\prime \prime}$ ), 127.9 ( $\left.\mathrm{t}, \mathrm{C}-2^{\prime \prime}, \mathrm{C}-6^{\prime \prime}\right), 127.7$ ( $\mathrm{t}, \mathrm{C}-3^{\prime \prime \prime}, \mathrm{C}-$ $7^{\prime \prime \prime}$ ), 126.7 (t, C-4"), 126.5 (q. After the starting material was fully consumed, the solvent was removed in vacuo and the excess of methyl cinnamate was removed by silica gel purification (petroleum ether/EtOAc 4:1, then EtOAc). The cycloadduct mixture was used directly for the next step. To a solution of the cycloadduct mixture ( 39.7 mg ) in $\mathrm{MeOH}(3 \mathrm{~mL})$ was added NaOMe solution ( $25 \mathrm{wt} \%$ in $\mathrm{MeOH}, 51 \mu \mathrm{~L}, 0.24 \mathrm{mmol}, 2.84$ equiv) and refluxed for 1 h . The reaction was terminated by the addition of $\mathrm{NH}_{4} \mathrm{Cl}$ (sat., aq.). The aqueous layers were extracted with EtOAc. The collected organic layers were washed with NaCl (sat., aq.), dried over $\mathrm{MgSO}_{4}$, filtered and concentrated in vacuo. The foamy ketone crude was directly used for the next step. A solution of $\mathrm{Me}_{4} \mathrm{NBH}-$ $(\mathrm{OAc})_{3}(140 \mathrm{mg}, 0.53 \mathrm{mmol}, 6.42$ equiv) and freshly distilled AcOH ( $50 \mu \mathrm{~L}, 0.86 \mathrm{mmol}, 10.4$ equiv) in dry $\mathrm{MeCN}(2 \mathrm{~mL})$ was prepared and stirred at rt for 10 min . To this solution was added ketone crude $(40.0 \mathrm{mg})$ in dry $\mathrm{MeCN}(1.4 \mathrm{~mL})$. The reaction was carried out under light exclusion and stirred for 19 h at rt . The reaction was terminated by the addition of NaK -tartrate (sat., aq.) and $\mathrm{NH}_{4} \mathrm{Cl}$ (sat., aq.). The layers were separated and the aqueous layers were extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The collected organic layers were washed with water and NaCl (sat., aq.), dried over $\mathrm{MgSO}_{4}$, filtered and concentrated in vacuo. The reaction mixture was degassed for 30 min , then cooled to $-5{ }^{\circ} \mathrm{C}$ and irradiated with UV light ( $\lambda_{\max }=365 \mathrm{~nm}$ ) until it no longer fluoresced greenish (20 h). Subsequently, the solvent was removed under reduced pressure. The remaining amount of methyl cinnamate was then removed by column chromatography (petroleum ether/EtOAc $9: 1 \rightarrow 1: 1$ ). Product E32 was obtained as a mixture of isomers as a yellowish solid ( 498 mg ) and used directly for the next step. The desired cycloadduct was obtained as a mixture of isomers as a yellowish solid ( 498 mg ). Without any further purification the product of the first step ( $498 \mathrm{mg}, 923 \mu \mathrm{~mol}, 1.00$ equiv) was dissolved in $\mathrm{MeOH}(34.2 \mathrm{~mL})$. Then NaOMe solution (499 $\mu \mathrm{L}, 25 \mathrm{wt} \%$ in $\mathrm{MeOH}, 3.00 \mathrm{mmol}, 3.25$ equiv) was added and the mixture was heated under refluxing conditions for 1 h . Subsequently, the reaction was terminated by the addition of $\mathrm{NH}_{4} \mathrm{Cl}$ solution (sat., aq.). The phases were separated and the aqueous phase was extracted with EtOAc ( $3 \times$ ). The organic phases were combined, dried over $\mathrm{MgSO}_{4}$, filtered and the solvent was removed under reduced pressure. Biological Evaluation: Virus Infection and Cytotoxicity. Cell Culture. Human hepatoma cells (HepG2) were cultured in Dulbecco's modified Eagle's medium (DMEM) (Invitrogen, Karlsruhe, Germany) supplemented with $10 \%$ fetal calf serum (FCS) (GE Healthcare), $100 \mu \mathrm{~g} / \mathrm{mL}$ of streptomycin, $100 \mathrm{IU} / \mathrm{mL}$ of penicillin (Invitrogen), 2 mM L-glutamine and $1 \%$ non-essential amino acids (Invitrogen) at $37^{\circ} \mathrm{C}$ in a $5 \%$ (v/v) $\mathrm{CO}_{2}$ incubator. Cells were grown on sterile collagen-coated (SERVA Electrophoresis GmbH, Heidelberg, Germany) culture plates. Huh7 cells were maintained in DMEM supplemented with $10 \%$ FCS, 2 mM L-glutamine, 0.1 mM nonessential amino acids and $1 \%$ penicillin/streptomycin.

African green monkey (Chlorocebus sp.) kidney cells (Vero E6, Collection of Cell Lines in Veterinary Medicine CCLV, Friedrich-Loeffler-Institut, Greifswald-Insel Riems, Germany) were grown and maintained in Eagle's minimal essential medium (MEM; Biochrom GmbH, Berlin, Germany) supplemented with $10 \%$ FCS (Biochrom GmbH, Berlin, Germany) and kept under a $5 \% \mathrm{CO}_{2}$ atmosphere at $37^{\circ} \mathrm{C}$.

Virus Isolates. SARS-CoV-2 isolate 2019 nnCoV Muc-IMB-1 (accession no. LR824570) ${ }^{48}$ was kindly provided by German Armed Forces Institute of Microbiology (Munich, Germany) and propagated on Vero E6 cells. The RVFV strain MP-12 (accession nos. DQ380154, DQ380208, DQ75404) ${ }^{49}$ was kindly provided by Richard Elliot (University of Glasgow, Centre for virus research, United Kingdom) and propagated on Vero E6 cells (Collection of Cell Lines in Veterinary Medicine, Friedrich-Loeffler-Institut, Germany). Viruses were cultivated and titrated on Vero E6 cells, and stock titers of approximately $10^{6}$ TCID50 $\mathrm{mL}^{-1}$ were achieved.

Plasmids and In Vitro Transcription. For HEV in vitro replication experiments, a plasmid construct harboring the HEV-3 Kernow-C1 p6 sequence coupled with a Gaussia luciferase reporter gene (here referred to as p6-Gluc; a kind gift of Suzanne Emmerson, National Institutes of Health, USA) was in vitro transcribed according to refs 50 and 51. In brief, $2 \mu \mathrm{~g}$ of linearized plasmid DNA was transcribed with T7 Polymerase (Promega) and capped using Ribom7G Cap Analog (Promega, Madison, WI) at $37^{\circ} \mathrm{C}$ for 4 h . Purified in vitro transcript was stored at $-80{ }^{\circ} \mathrm{C}$. For CHIKV assays, the infectious clone CHIKV LR2006-OPY1 (ECSA genotype) expressing GFP under the control of a subgenomic promoter was used as described previously. ${ }^{52}$ In brief, infectious virus was produced by in vitro transcription followed by electroporation of RNA into BHK-21 cells. Supernatant was collected 48 h after electroporation and titrated on HEK 293T.

Dose-Dependent Replication Assay (HEV). For transfection of the p6-Gluc replicon, HepG2 cells were electroporated as previously reported. ${ }^{53}$ Briefly, $5 \times 10^{6}$ cells were electroporated in $400 \mu \mathrm{~L}$ Cytomix containing 2 mM adenosine triphosphate and 5 mM glutathione with $5 \mu \mathrm{~g}$ of in vitro transcribed HEV RNA using the Gene Pulser Xcell system (Bio-Rad, Munich, Germany). Afterward, transfected cells were transferred into 12.1 mL fresh DMEM culture medium and seeded onto 96 -well plates at a nonconfluent density of $2 \times 10^{4}$ cells/well (in $50 \mu \mathrm{~L}$ volume) or at confluency ( $4 \times 10^{4}$ cells/ well). Four hours post transfection (p.t.), cells were treated with various compound concentrations ranging from 0.15 nM to 1000 nM in a 3 -fold serial dilution. At indicated time points p.t., the supernatant was collected and used to examine the effect of rocaglamides derivatives on HEV replication. Samples were stored at $4{ }^{\circ} \mathrm{C}$ until luminometer reading.

Gaussia Luciferase Assay. To determine Gaussia luciferase activity, $20 \mu \mathrm{~L}$ of harvested supernatant was added per well on a 96 -well LUMITRAC 600 plate, followed by the addition of $60 \mu \mathrm{~L}$ of Coelenterazine. Luminescence was detected for 1 s with a Centro $\mathrm{XS}^{3}$ LB 960 luminometer (Berthold Technologies) after shaking for 2 s . Samples were measured in triplicate and read sequentially.

Antiviral Assay (SARS-CoV-2 and RVF). To evaluate the efficiency of the described derivates in vitro, Vero E6 cells from overnight cultures were infected with SARS-CoV-2 or RVFV strain MP-12 at a multiplicity of infection (MOI) of 0.1. After infection, the wells were incubated at $37{ }^{\circ} \mathrm{C}$ under a $5 \% \mathrm{CO}_{2}$ atmosphere for 60 min and were then washed with phosphate-buffered saline. Fresh culture medium (MEM supplemented with 5\% FCS) containing different compound dilution levels ( $1: 3$ dilution; start concentration $1 \mu \mathrm{M}$ ) was added. The supernatants were collected at 24 h post infection (hpi) or 48 hpi including four biological replicates.

Quantitative Real-Time RT-PCR (RT-qPCR) Assay. RNA from SARS-CoV-2 and RVFV MP-12 was extracted from all supernatants using the NucleoMag Vet kit (MachereyNagel, Düren, Germany) for a magnetic-bead based isolation of viral RNA according to the manufacturer's instructions in an elution volume of $100 \mu \mathrm{~L}$. SARS-CoV-2 RNA was detected by the E-gene Sarbeco 6-carboxyfluorescein RT-qPCR, ${ }^{54}$ detection limit 1 genome copy per $\mu \mathrm{L}$ RNA eluate. The presence of RVF MP-12-derived RNA was analyzed with qRT-PCR ${ }^{55}$ using the QuantiTect Probe RT-PCR Kit (Qiagen, Hilden, Germany).

Infection Assay (CHIKV). For infections assays, $2 \times 10^{4}$ Huh7 cells per well in a 96-well plate were seeded 24 h prior to infection. $100 \mu \mathrm{~L}$ CHIKV ECSA 3'-GFP was added at a MOI 2.5 (based on HEK 293T TCID50) to each well and incubated for 1 h at $37{ }^{\circ} \mathrm{C}$. Meanwhile, compounds were serially diluted in growth medium from 2000 nM to 0.3 nM and $100 \mu \mathrm{~L}$ of compound dilution was added to the designated wells containing virus inoculum in triplicates. GFP expression was documented ( $10 \times$ magnification, 300 ms exposure) until 48 h post infection using the IncuCyte S3 imaging platform (Sartorius). Images were analyzed for total GFP fluorescence intensity per well at 24 and 48 hpi using the manufacturer's basic analyzer tool.

Cell Viability Assay. Cell viability was assessed by 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. Therefore, $0.5 \mathrm{mg} / \mathrm{mL}$ MTT substrate (Sigma) diluted in DMEM was added to cells and incubated at $37{ }^{\circ} \mathrm{C}$ and $5 \% \mathrm{CO}_{2}$ for $1-2 \mathrm{~h}$. To solubilize MTT reduction product, medium was removed and replaced with $50 \mu \mathrm{~L}$ DMSO/well. Absorbance was measured at 570 nm with a micro-absorbance reader (Tecan). As background control, cells were treated with $70 \%$ ethanol for 10 min .

To measure cellular metabolic activity in SARS-CoV-2 and RVFV infected cells, MTT assay was performed with the Cell Proliferation Kit (Roche, Basel, Schweiz) according to manufacturer's recommendations. Briefly, Vero E6 cells ( $1.8 \times 10^{5}$ cells $/ \mathrm{mL}$ ) were seated on a 96-well plate, and after 24 h the different dilutions of the compounds were added and incubated for 24 or 48 h . Afterward, $10 \mu \mathrm{~L}$ MTT was added and incubated for another 4 h , then the solubilization solution was added and the spectrophotometrical absorbance was measured after overnight incubation.

Statistics. Data on dose-dependent inhibition of HEV replication were fitted using a nonlinear regression model and $\mathrm{EC}_{90} / \mathrm{CC}_{50}$ values were calculated according to a four-parameter log-logistic model. For compounds that did not reach the half-maximum cytotoxic concentration in the dose-response assay, their $\mathrm{CC}_{50}$ values were assigned a default value of 1000 (which was the highest concentration tested). These values were then used to calculate selective indices. To determine $\mathrm{EC}_{50}$ and $\mathrm{EC}_{90}$ values, Prism GraphPad calculated best-fit values, which were then used to determine SI values. To calculate $\mathrm{EC}_{90}$ values in SARS-CoV-2 and RVFV experiments, the virus RNA load determined for nontreated virus-infected cells was set to $100 \%$ and RNA values obtained for treated cells were normalized to this value. Data analysis was performed in GraphPad Prism v9.3.1 (La Jolla, California, USA, www.graphpad.com).

## Author Contributions

${ }^{\ddagger}$ C.V. and G.S. contributed equally. E.S., M.H.G. and A.K. conceived the core of the study. A.K. supervised the chemical syntheses and C.V. and G.S. designed and carried them out. E.S., M.H.G., M.E., G.G., and Y.B. supervised the biological studies. M.K. carried out in vitro testing with the hepatitis E virus. M.B. carried out in vitro testing with the CHIKV virus. S.W. and C.M.H. carried out in vitro testing with the SARS-CoV-2 virus and RVF. The manuscript was written through contributions of all authors. All authors have given approval to the final version of the manuscript.

## Funding

E.S. was supported by the German Federal Ministry of Health (ZMVI1-2518FSB705) and a grant of the German Centre for Infection Diseases (DZIF). E.S., M.H.G. and A.K. were
supported by the German Ministry of Education and Research (BMBF, project SILVIR: 16GW0202). G.G. received funding from the Lower Saxony Ministry of Science and Culture (15-76251-1-2/23 (511/2023)).

## Notes

None of the funding organizations were involved in the collection, analysis and interpretation of data, writing of the research article, or the decision to submit the article for publication.
The authors declare no competing financial interest.

## ACKNOWLEDGMENTS

We thank Joey Reverey, Johannes Kühn, Matthias Schrader, David Berger and Nils Bode for their expert assistance in the synthesis of new rocaglates. We would also like to thank Laura Schmid, Birke Lange and Jasmin Nowacki for their excellent technical assistance. A.K. thanks the Wenner-Gren Foundation for funding a sabbatical stay at Uppsala University (Sweden). The foundation supported the collaboration with Prof. Mate Erdelyi, who provided helpful ideas on halogen bonding.

## ABBREVIATIONS USED

4-DMAP, 4-dimethylaminopyridine; Ac, acetyl; APCI, atmos-pheric-pressure chemical ionization; Bn, benzyl; BHK-21, baby hamster kidney cells; Bz, benzoyl; CHIKV, Chikungunya virus; DMEM, Dulbecco's modified Eagle medium; DMSO, dimethyl sulfoxide; EDC, 1-ethyl-3-(3-(dimethylamino)propyl)carbodiimide; EI, electron ionization; ESI, electrospray ionization; GC, gas chromatography; GFP, green fluorescent protein; Gluc, Gaussia luciferase; HEV, hepatitis E virus; HEK 293T, human embryonic kidney cells; HOBt , hydroxybenzotriazole; HPLC, high-pressure liquid chromatography; Pr , isopropyl; LiHMDS, lithium bis(trimethylsilyl)amide; mCPBA, metachloroperoxybenzoic acid; Me, methyl; MOM, methoxymethyl; MS, mass spectrometry; MTT, 3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyltetrazolium bromide; NMR, nuclear magnetic resonance; OTf, triflate; Ph , phenyl; $p \mathrm{TsOH}$, paratoluenesulfonic acid; $R_{f}$, retention factor; RNA, ribonucleic acid; RVF, Rift Valley fever virus; Sars-CoV-2, severe acute respiratory syndrome coronavirus type 2 ; TBS, tert-butyldimethylsilyl; TCID50, tissue culture infection dose 50; THF, tetrahydrofuran; TMS, trimethylsilyl; TFE, 2,2,2-trifluoroethanol; TLC, thin-layer chromatography; UV, ultraviolet
