Abstract

Abiotic stresses limit plant growth, metabolism and productivity. In this study two different approaches were carried out to enhance plant tolerance to abiotic stresses. The first approach aimed to characterize biochemically a glycolate dehydrogenase (*CrGlcDH*), a key enzyme in *Chlamydomonas reinhardtii* photorespiration. Photorespiration is now believed to be a part of stress response in plants through preventing accumulation of reactive oxygen species (ROS) and protecting photosynthesis from photoinhibition. *CrGlcDH* is different in structure from the *GlcDH* enzymes of heterotrophic prokaryotes and the glycolate oxidases of higher plants. In this study, *CrGlcDH* was recombinantly overexpressed, purified and its enzymatic properties were studied. It was found to use D -lactate, but not L -lactate, as an alternative substrate with similar catalytic proficiency compared to glycolate. Other short-chain organic acids were only very slowly oxidized. Only the artificial electron acceptors DCIP and PMS, but neither flavine mono- or dinucleotides nor nicotineamide dinucleotides or cytochrome *c*, were used as electron acceptors by the recombinant enzyme. The enzyme was sensitive to $CuSO_4$ suggesting function of reactive sulfhydryl groups in catalysis. Accordingly, mutational analysis of a putative Fe-S cluster indicated an important function of this domain in catalysis. Evolutionary sequence analysis revealed that *CrGlcDH* belongs to a so far uncharacterized group of enzymes that was only found in chlorophytes and some proteobacteria. Other prokaryotic *GlcDH* enzymes were only distantly related. Moreover, the most related proteobacterial homologue from *Desulfovibrio vulgaris* was also recombinantly overexpressed and purified. It was found to be active with D -lactate, but not glycolate as a substrate.

The second approach in this study was to introduce a novel pathway in plants for cyanide detoxification. Cyanide is a strong inhibitor of diverse metabolic reactions and easily absorbed by organisms. However, cyanide is also a byproduct of plant and microbial metabolism. This is why these groups of organisms contain pathways for cyanide detoxification. Large amounts of cyanides are also produced by industries and are today mostly removed by physical and chemical methods. Phytoremediation can provide an alternative to these techniques, but existing cyanide concentrations at contaminated sites often exceed the capacities of plant metabolism. In this study, a bacterial cyanidase together with a plant formate dehydrogenase were introduced to *Arabidopsis thaliana* in order to establish a synthetic pathway for cyanide degradation. Simultaneous overexpression of both enzymes would ultimately result in the formation of CO_2

ABSTRACT

and NH_3 from cyanide. Both enzymes were targeted to chloroplasts and shown to be active *in planta*. Growth on cyanide was tested for seedlings germinating on agar, plants in hydroponics, and plants growing in sand. In all three assays, plants overexpressing the synthetic pathway for cyanide degradation showed enhanced growth and biomass accumulation compared to controls. In addition, gas exchange measurements confirmed enhanced stress resistance of transgenic plants and suggested that cyanide degradation to CO_2 increased the leaf internal CO_2 concentration.

Zusammenfassung

Abiotischer Stress limitiert Wachstum, Metabolismus und Produktivität von Pflanzen. Im Rahmen dieser Arbeit wurden zwei unterschiedliche Ansätze zur Erhöhung der Toleranz von Pflanzen gegen abiotischen Stress getestet. Im ersten Ansatz wurde eine photorespiratorische Glycolatdehydrogenase (*CrGlcDH*) aus *Chlamydomonas reinhardtii* biochemisch charakterisiert. Photorespiration wird heute als ein Bestandteil der Stressantwort von Pflanzen gesehen, da dieser Stoffwechselweg die Akkumulation reaktiver Sauerstoffspezies vermindert und die Photosysteme vor Photoinhibition schützt. *CrGlcDH* unterscheidet sich in der Struktur von den Glycolatdehydrogenasen heterotropher Eukaryoten und der Glycolatoxidasen höherer Pflanzen. In dieser Arbeit wurde *CrGlcDH* rekombinant überexprimiert, aufgereinigt und enzymatisch charakterisiert. D-Lactat, aber nicht L-Lactat, wurde als alternatives Substrat mit zu Glycolat vergleichbarer katalytischer Effizienz akzeptiert. Andere kurzkettige organische Säuren wurden nur sehr langsam oxidiert. Die artifiziellen Elektronenakzeptoren DCIP und PMS, aber weder Flavin mono- und dinucleotide noch Nikotinamid-dinucleotide oder Cytochrom c wurden als Elektronendonatoren akzeptiert. Das Enzym wurde durch CuSO_4 inhibiert, was für eine Funktion von Sulfhydryl-Gruppen bei der Katalyse spricht. Entsprechend konnte durch Mutationsanalysen eine wichtige Rolle eines Fe-S-Clusters bei der Katalyse belegt werden. Durch evolutionäre Sequenzanalysen wurde *CrGlcDH* einer bisher unbeschriebenen Gruppe von Enzymen zugeordnet, die nur in Chlorophyten und einigen Protobakterien vorkommen. Andere prokaryotische *GlcDH* Enzyme zeigten nur geringe Homologien zu *CrGlcDH*. Das am nächsten verwandte proteobakterielle Homolog aus *Desulfovibrio vulgaris* zeigte ebenfalls Aktivität mit D-Lactat als Substrat, aber nicht mit Glycolat.

In einem zweiten Ansatz wurde ein neuer Stoffwechselweg zum Zyanid-Abbau in Pflanzen etabliert. Zyanid ist ein starker Inhibitor zahlreicher metabolischer Reaktionen und wird von Organismen leicht aufgenommen. Auf der anderen Seite ist Zyanid auch ein natürliches Nebenprodukt des Metabolismus von Pflanzen und Mikroorganismen. Daher enthalten diese Organismengruppen Stoffwechselwege zum Zyanid-Abbau. Große Mengen an Zyanid werden auch in industriellen Prozessen erzeugt und heute zumeist über physikalische oder chemische Methoden entsorgt. Phytoremediation könnte als Alternative zu diesen Techniken genutzt werden, aber die Konzentrationen an kontaminierten Standorten übersteigen häufig die metabolische Leistungsfähigkeit von Pflanzen. Im Rahmen dieser Arbeit wurden eine bakterielle

ZUSAMMENFASSUNG

Cyanidase und eine pflanzliche Formatdehydrogenase in *Arabidopsis thaliana* überexprimiert, um einen synthetischen Stoffwechselweg zum Zyanidabbau zu etablieren. Die gleichzeitige Überexpression beider Proteine würde letztlich zu einem Abbau des Zyanids zu CO₂ und NH₃ führen. Beide Enzyme wurden in Chloroplasten lokalisiert und die *in planta* Aktivität wurde nachgewiesen. Das Wachstum von Keimlingen unter Zyanidstress wurde auf Agar, in hydroponischer Kultur, und in Sand als Substrat getestet. In allen drei Ansätzen zeigten Pflanzen, die den synthetischen Stoffwechselweg zum Zyanidabbau überexprimierten, eine erhöhte Biomasseakkumulation im Vergleich zu Kontrollen. Gaswechsellmessungen bestätigten die verbesserte Stressresistenz und ergaben Hinweise auf eine erhöhte CO₂ Konzentration in Blättern als Resultat der Zyaniddegradation.

1. Introduction

1.1. Photosynthesis

Photosynthesis is an important process for all living forms on earth. It is the process by which photoautotrophic organisms capture light energy and use it to convert atmospheric carbon dioxide and water into carbohydrates. The food that we eat, the oxygen that is required for all aerobic organisms, the fuel that is required for energy production, and the fibers that we wear are resulting from photosynthesis (Blankenship, 2010). Photosynthesis is generally divided up into two parts: the light reactions and the carbon reactions.

The light dependent reactions (Figure 1) are the processes in which the light is captured and conserved in the form of chemical bonds (Sugar). These processes take place in the thylakoid membrane of the chloroplasts. This is performed by photo-system I (PSI) and photo-system II (PSII) (Järvi et al., 2013). In the reaction center of PSII an electron from one of the chlorophylls is excited and subsequently transferred through a series of acceptors in the electron transport chain. The linear electron transport chain builds up a proton gradient over the thylakoid membrane, which is used to produce energy via converting ADP to ATP. In addition, the reducing agent NADPH is produced during the electron transport through PSI. The light reactions serve to produce the energy carriers which are further used in the carbon reactions to fix atmospheric CO₂ (Järvi et al., 2013).

The carbon reactions do not directly need light in order to occur, but they need the products of the light reaction (ATP and NADPH). The light independent reactions occur in the stroma of the chloroplast. During these reactions, the reducing power and energy equivalents (ATP and NADPH) provided by the light reactions are required for CO₂ assimilation. Most higher plants assimilate carbon dioxide through the C₃-photosynthetic pathway and thus are known as C₃ plants (Ku et al., 1999). The CO₂ assimilation pathway in C₃ plants is known as the Calvin cycle (Figure 3). The Calvin cycle proceeds in three stages, carboxylation, reduction and regeneration. During the carboxylation reaction, a molecule of CO₂ is covalently linked to a five-carbon skeleton called ribulose biphosphate (RuBP) producing an unstable six-carbon intermediate that immediately breaks down into two molecules of the three-carbon compound phosphoglycerate (PGA). The carbon that was a part of inorganic CO₂ is now part of the carbon skeleton of an organic molecule.

INTRODUCTION

Figure 1. Schematic diagram for the transfer of electrons and protons in the thylakoid membrane. The figure was taken from Plant Physiology fifth edition (Taiz and Zeiger, 2010)

CO_2 fixation is catalyzed by a complex enzyme consisting of eight large subunits and eight small subunits (Miziorko and Lorimer, 1983; Parry, 2003; Whitney et al., 2011) known as ribulose-1,5-bisphosphate carboxylase/oxygenase (Rubisco, EC 4.1.1.39). In addition to CO_2 fixation, Rubisco accepts O_2 as a competitor substrate (Figure 2). Depending of certain conditions such as temperature and CO_2/O_2 ratio, the oxygenation reactions (photorespiration, see 1.2) of Rubisco are estimated to be quarter or even higher of its activity (Sharkey, 1988). Rubisco is produced in huge amount in higher plants to compensate for its slow activity (Tcherkez et al., 2006), as it can make up as much as 30-50% of total leaf protein in C_3 plants (Parry, 2003). During the reduction phase, the carboxylated compound is reduced on the expense of the photochemically derived ATP and NADPH. The PGA is converted to glyceraldehyde-3-phosphate (G3P), another three carbon compound. For every six molecules of CO_2 that enter the Calvin cycle, two molecules of G3P are produced. Some of the molecules of G3P, however, are used to synthesize glucose and other organic molecules.

INTRODUCTION

Figure 2. Schematic overview of the bi-functions (CO_2/O_2 fixation) of Rubisco in photosynthetic organisms.

Figure 3. The carbon reactions pathway in C_3 plants (Calvin cycle). ATP, adenosine triphosphate. ADP, adenosine diphosphate. CO_2 , carbon dioxide. NADPH, nicotinamide adenine dinucleotide phosphate (Reduced form). NADP^+ , nicotinamide adenine dinucleotide phosphate (Oxidized form). The figure was taken from plants physiology fifth edition (Taiz and Zeiger, 2010).

INTRODUCTION

During the regeneration phase, the CO₂ acceptor RuBP re-forms. Most of the G3P produced during the Calvin cycle are used to regenerate RuBP.

Ten molecules of the three-carbon compound G3P eventually form six molecules of the five-carbon compound ribulose phosphate (RP) which is then phosphorylated to produce RuBP, the starting compound for the Calvin cycle.

1.2. Photorespiration

Photorespiration occurs in all oxygen (O₂)-producing photosynthetic organisms (Bauwe et al., 2010). Biochemically, photorespiration begins with O₂ substituting for CO₂ in the first reaction of the photosynthetic CO₂ fixation that is catalyzed by Rubisco (Leegood et al., 1995; Wingler et al., 2000). The reductive reaction (Carboxylation reaction, or CO₂ fixation) of Rubisco enzyme is known as C₃ or Calvin cycle (See 1.1), and the oxidative reaction (O₂ fixation) is known as C₂ or photorespiration (Leegood et al., 1995; Wingler et al., 2000). The carboxylation of RubP produces two molecules of 3-phosphoglycerate (PGA) while its oxygenation yields one molecule of PGA and one molecule of phosphoglycolate (PG) (Andersson, 2008). PG is a toxic compound, it inhibits the Calvin-cycle enzyme triose- phosphate isomerase, thus it should be metabolized rapidly (Norman and Colman, 1991; Tolbert, 1997).

1.3. The photorespiratory pathway in higher plants (C₂ cycle)

In higher plants, metabolism of PG compound is achieved via several enzymes distributed in three different compartments: chloroplast, peroxisome, and mitochondria (Foyer et al., 2009; Bauwe et al., 2010). In the chloroplast, PG is dephosphorylated to glycolate through a highly specific enzyme known as phosphoglycolate phosphatase (PGLP) (Somerville and Ogren, 1979). In addition to the plastidial PGLP enzyme (At5g36700), *Arabidopsis thaliana* also has a second enzyme in the cytosol, but only knockout mutants of the plastidial enzyme result in a photorespiratory phenotype and require CO₂-enriched environment to survive (Schwarte and Bauwe, 2007). PGLP was reported as a light-induced gene (Foyer et al., 2009). Biochemical studies were performed on purified PGLP proteins from various organisms revealed the requirement of Mg²⁺ and Cl⁻¹ for PGLP activity (Husic and Tolbert, 1984; Norman and Colman, 1991). The produced glycolate is transported from the chloroplast through a glycolate-glycerate antiporter and enters the peroxisome via porin-like channels (Reumann and Weber, 2006; Pick et al., 2013).

INTRODUCTION

In the peroxisomes, glycolate is oxidized in an irreversible reaction into equimolar amounts of glyoxylate and H₂O₂. Glycolate oxidation is catalyzed by glycolate oxidase (GOX, EC 1.1.3.15) (Volokita et al., 1987). In Arabidopsis plants five genes were reported to encode GOX protein, three of them are localized in the peroxisome (Reumann et al., 2004; Reumann and Weber, 2006). GOX-mutants in rice plants (Xu et al., 2009) and in maize (Zelitch et al., 2009) require elevated CO₂ for survival, while no GOX-mutants were identified in Arabidopsis plants (Somerville and Ogren, 1982). Moreover, studies using down-regulated GOX mutants in tobacco plants revealed the potential regulatory effect of GOX proteins on photosynthesis (Xu et al., 2009). Furthermore, GOX protein was found to be induced during the pathogen infection (Taler et al., 2004). The H₂O₂ generated as a by-product during glycolate oxidation is detoxified by catalase (CAT, EC 1.11.1.6) in the peroxisome (Tolbert, 1997; Queval et al., 2007; Foyer et al., 2009). Three different CAT genes were identified in Arabidopsis, but only one gene (CAT2, At4g35090) was found to involve in photorespiration cycle (Queval et al., 2007). CAT2 was reported as light-induced gene and clock-regulated (Induced in the morning) (Zhong et al., 1997; Queval et al., 2007). Arabidopsis plants with CAT2-knock-out mutant showed reduction in rosette biomass and activation of oxidative signaling pathway (Queval et al., 2007). Glyoxylate is then transaminated to glycine. In Arabidopsis glyoxylate is transaminated to glycine through one of two parallel reactions catalyzed by glutamate:glyoxylate aminotransferase (GGAT, EC 2.6.1.4) or serine:glyoxylate aminotransferase (SGAT, EC 2.6.1.45). Two GGAT genes (At1g23310 encoding GGAT1 and At1g70580 encoding GGAT2) were identified in Arabidopsis (Igarashi et al., 2003, 2006). It was reported that each of GGAT1 and GGAT2 contributes in the total GGAT activity in photorespiration (Igarashi et al., 2006). In Arabidopsis SGAT is encoded by a single gene (At2g13360). SGAT knock-out mutants in Arabidopsis (Somerville and Ogren, 1980; Liepman and Olsen, 2001) or barley (Murray et al., 1987) were lethal under ambient air conditions.

In the mitochondria, two molecules of glycine are required to generate one molecule of serine by the combined action of two enzymatic complexes: glycine decarboxylase (GDC) and serine hydroxymethyltransferase (SHMT, EC. 2.1.2.1) (Peterhansel et al., 2010). Decarboxylation of one glycine molecule produces one molecule each of CO₂, NH₃, NADH, and 5,10 methylene tetrahydrofolate (CH₂-THF) (Oliver, 1994; Douce et al., 2001). GDC is a complex enzyme consisting of four different subunits (P (EC 1.4.4.2), H, T (EC 2.1.2.10), and L (EC 1.8.1.4)). In

INTRODUCTION

Arabidopsis plants, eight different genes were identified for GDC complex protein, two genes for each subunit (P-protein (At4g33010 and At2g26080) and L-protein (At3g17240 and At1g48030), three genes for H-protein (At2g35370, At2g35120 and At1g32470) and one gene for T-protein (At1g11860)) (Bauwe and Kolukisaoglu, 2003). Enriched CO₂ air was not able to rescue Arabidopsis plants with double knock-out mutants in the two genes encoding the P-subunit (Engel et al., 2007) suggesting that GDC has a potential function in nucleic acids and amino acids metabolism (Cossins and Chen, 1997). The SHMT combines methylene-THF with a second molecule of glycine to produce one molecule of serine and regenerate THF (Leegood et al., 1995). In Arabidopsis, the SHMT is encoded by a single gene (At4g37930). Knock-out mutants of SHMT require elevated CO₂ to survive (Voll et al., 2006).

Back to the peroxisome, serine generated in the mitochondria goes back to the peroxisome and is converted to glycerate through the action of SGAT (See above: in the peroxisome) that produces hydroxypyruvate (HP). HP is reduced by NADH-dependent hydroxypyruvate reductase (HPR1, EC 1.1.1.29) to glycerate. In Arabidopsis, HPR1 is encoded by a single gene (At1g68010) (Givan and Kleczkowski, 1992). HPR1 knock-out mutants in Arabidopsis (Timm et al., 2008) and barley (Murray et al., 1989) do not show the photorespiratory phenotype suggesting that an alternative pathway for the conversion of hydroxypyruvate to glycerate may exist (Peterhansel et al., 2010). Finally, glycerate is transported back to the chloroplast then phosphorylated to form PGA by catalysis of _D-glycerate 3-kinase (GLYK, EC 2.7.1.31) at expense of ATP. In Arabidopsis, GLYK is encoded by a single gene (At1g80380) and knock-out mutants show the photorespiratory phenotype (Boldt et al., 2005).

INTRODUCTION

Figure 4. The major photorespiratory pathway. DiT1 and DiT2: dicarboxylate transporter 1 and 2; CAT: catalase; GDC: glycine decarboxylase; GGAT: glutamate:glyoxylate aminotransferase; GLYK: glycerate kinase; GO: glycolate oxidase; GOGAT: glutamate:oxoglutarate aminotransferase; GS: glutamine synthetase; HPR1: peroxisomal hydroxypyruvate reductase; HPR2: cytosolic hydroxypyruvate reductase; PGP: phosphoglycolate phosphatase; Rubisco: ribulose-1,5-bisphosphate carboxylase/oxygenase; RubP: ribulose-1,5- bisphosphate; SGAT: serine-glutamate aminotransferase; SHMT: serine hydroxymethyl transferase; THF: tetrahydrofolate; 5,10-CH₂-THF: 5,10- methylene-THF; and 3-PGA: 3-phosphoglycerate. The dashed line represents the reductive and regenerative phases of the Calvin Cycle. The figure was taken from (Maurino and Peterhansel, 2010).

1.4. Glycolate and glyoxylate metabolism in other organisms

Several heterotrophic bacteria have been reported to use glycolate as a carbon source for growth (Edenborn and Litchfield, 1985). Heterotrophic bacteria oxidize glycolate to glyoxylate by catalysis of glycolate oxidase (GlcDH, see 1.6). Glyoxylate is then metabolized through various mechanisms: the glycerate pathway via tartronic semialdehyde (Hansen and Hayashi, 1962), the β -hydroxyaspartate pathway (Kornberg and Morris, 1965), and dicarboxylic acid pathway (Kornberg and Sadler, 1960). In the glycerate pathway, glyoxylate carboxylase catalyzes the formation of tartronic semialdehyde from two glyoxylate molecules and CO₂ molecule is

INTRODUCTION

released. Afterwards, tartronic semialdehyde is reduced to glycerate by tartronic semialdehyde reductase. Finally, glycerate is phosphorylated to form phosphoglycerate by glycerate kinase (Kornberg and Sadler, 1961). In the β -hydroxyaspartate pathway, oxaloacetate is produced as an end product of glyoxylate utilization. The erythro β -hydroxyaspartate compound was reported as a key intermediate compound in glyoxylate metabolism through this pathway (Kornberg and Morris, 1965). Dicarboxylic acid pathway was also reported in bacteria for glyoxylate metabolism and producing formate as an end product by catalysis of malate synthase G (Kornberg and Sadler, 1960).

In cyanobacteria, glycolate is produced from the dephosphorylation of phosphoglycolate that is generated from the oxygenative activity of Rubisco as in higher plants (See 1.1). Studies on *Synechocystis sp* revealed the existence of three different routes for glyoxylate metabolism (Figure 5). Beside the bacterial glycerate pathway, all the enzymes in the C_2 cycle (See 1.3) in higher plant were determined. In addition, decarboxylation of glyoxylate via oxalate was also reported (Eisenhut et al., 2008).

In green algae, several studies revealed the existence of most C_2 cycle genes (Tural and Moroney, 2005). However, two different genes were identified for glycolate oxidation among green algae. The charophycean algae were found to possess microbodies similar to the leaf peroxisomal type containing an active GOX enzyme (Stabenau et al., 2003; Stabenau and Winkler, 2005). While in *Chlamydomonas* and several other chlorophyta glycolate is oxidized to glyoxylate by a mitochondrial glycolate dehydrogenase GlcDH (See 1.6) (Nakamura et al., 2005; Stabenau and Winkler, 2005).

Figure 5. A scheme describing the different routes for PG metabolism in *Synechocystis sp.* The figure was taken from Eisenhut et al (2008).

1.5. Pros and Cons of photorespiration

Since its discovery in early 1960s by Krotkov (Hew and Krotkov, 1968), photorespiration in all oxygen (O_2) producing photosynthetic organisms remains controversial. Photorespiration undoubtedly represents a potential limitation on carbon gain in C_3 plants, and ultimately, crop yields. The oxygenation reactions catalyzed by Rubisco represent a wasteful process in plants because of its association with carbon and nitrogen loss (Ogren, 1984). During the oxygenation reaction, the RuBP the main precursor for CO_2 fixation is consumed and a toxic PG compound is produced. Recycling of the PG compound consumes ATP and reducing equivalents in the form of NAD/(P)H (Sage, 2004). The CO_2 release in the mitochondria during photorespiration results in 25% loss of the carbon from PG compound. Moreover, NH_3 is lost in this cycle that has to be refixed (Leegood et al., 1995).

Despite of the negative aspects mentioned above, the predominating view on photorespiration has completely changed since the pathway is recognized as an integral element of primary carbon metabolism that interacts with many other pathways (Maurino and Peterhansel, 2010). Moreover, photorespiration has been suggested to play an important role in maintaining the electron flow in the chloroplast. Photorespiration protects the stroma from its over reduction and

thus photoinhibition that might occur under stress conditions such as high-light, drought, salt-stress (Osmond et al., 1997; Wingler et al., 2000; Weise et al., 2006; Miller et al., 2010a)

1.6. Glycolate oxidizing enzymes

Glycolate oxidation to glyoxylate is an essential step in photorespiration in all photosynthetic organisms (Maurino and Peterhansel, 2010). In addition, glycolate can be used as a carbon source by various heterotrophic bacteria (Lau et al., 2007). Although the reaction is highly conserved, the different classes of organisms use different enzymes for glycolate oxidation.

As described previously (See 1.3), land plants and charophytes, their nearest sister group within green algae, use GOX for glycolate oxidation (Vlokita et al., 1987; Stabenau et al., 2003; Hagemann et al., 2013). The GOX enzyme is a flavin mononucleotide (FMN) dependent enzyme that is using molecular oxygen as the terminal electron acceptor. This enzyme is using *L*-lactate as an alternative substrate and cyanide inhibitors have no effect on its activity.

In *E. coli* and other prokaryotes, a completely unrelated enzyme named glycolate dehydrogenase (*EcGlcDH*, EC 1.1.99.14) is used for glycolate oxidation. The enzyme is made up from three protein subunits encoded by the *glcD*, *glcE*, and *glcF* open reading frames of the *glc* operon (Sallal and Nimer, 1989; Pellicer, 1999). *EcGlcDH* accepts *D*-lactate, but not *L*-lactate, as an alternative substrate and is highly sensitive to cyanide (Lord, 1972). In the photosynthetic cyanobacterium *Synechocystis*, two genes encoding homologues to *glcD* were identified, but homologues to *glcE* and *glcF* were not described so far (Eisenhut et al., 2008). Double knockout of the two *glcD* genes resulted in a disruption of photorespiration and a lethal phenotype that could only be rescued at high CO₂ concentrations (Eisenhut et al., 2008).

Furthermore, the chlorophyte green alga *Chlamydomonas reinhardtii* was reported to encode a protein (*CrGlcDH*, gi|159474536) with homology to *EcGlcDH*. A *Chlamydomonas* mutant in this gene was reported to require enriched CO₂ environment for growth (Nakamura et al., 2005) suggesting that photorespiration was disrupted in this mutant similar to what has been observed in cyanobacteria. Molecular characterization of *CrGlcDH* was reported by Nakamura et al (2005). Interestingly, the amino acids sequence of *CrGlcDH* has high homology to *glcD* in the N-terminal and to *glcF* in the C-terminal part of the protein sequence. This suggested that two of the three subunits of *EcGlcDH* were merged in this enzyme (Nakamura et al., 2005).

1.7. Synthetic pathways to reduce photorespiratory losses

Considerable effort has been invested over the past decades to reduce photorespiratory losses either through attempts to modify Rubisco specificity (CO_2/O_2) or through modifying photorespiratory metabolism (Spreitzer and Salvucci, 2002; Kebeish et al., 2007; Andersson, 2008; Carvalho et al., 2011; Maier et al., 2012). In theory, disruption of the photorespiratory pathway should enhance CO_2 fixation and consequently growth. However, knockout mutants of several photorespiratory genes resulted in strongly retarded growth revealing its importance (See 1.3). Three different approaches were suggested by genetic engineering for modifying the photorespiratory pathway (Kebeish et al., 2007; Carvalho et al., 2011; Maier et al., 2012).

Kebeish et al (2007) proposed the installation of a bypass (Bypass1, Figure 6) of 5 different bacterial proteins targeted to the chloroplast of Arabidopsis plants in order to reduce photorespiratory losses. Bypass1 starts with glycolate and ends with glycerate. Glycolate is oxidized by the three subunits glycolate dehydrogenase enzyme from *E.coli* (*EcGlcDH*) (See 1.6). Afterwards, two glyoxylate molecules (C_2 compound) are merged to form tartronic semialdehyde (C_3 compound) by catalysis of the bacterial glyoxylate carboligase enzyme (GCL) and CO_2 is released. Finally, tartronic semialdehyde is reduced to glycerate by tartronic semialdehyde reductase (TSR). Bypass1 pathway differs from the original photorespiratory pathway in shifting CO_2 release into the vicinity of Rubisco in the chloroplast. This might result in increasing the CO_2/O_2 ratio, and as a consequence should decrease oxygenation of RuBP. Furthermore, ammonia release is avoided that maintains the energy required for refixation.

INTRODUCTION

Table 1. Comparison of the enzymatic reactions of photorespiration and the three bypasses.

	Reaction	Photorespiration	Bypass 1	Bypass 2	Bypass 3
1	Phosphoglycolate-dephosphorylation	PGLP	PGLP	PGLP	PGLP
2a	Glycolate-oxidation	GOX	GlcDH	GOX	GOX
2b	H ₂ O ₂ - detoxification	CAT	-	CAT	CAT
3	Transamination	GGAT	-	-	-
4a	Decarboxylation	GDC, SHMT	GCL	GCL	ME, PDH
4b	NH ₃ -release	GDC, SHMT	-	-	-
5	Transamination	SGAT	-	-	-
6	Reduction	HPR	TSR	HPR	-
7	Glycerate-phosphorylation	GK	GK	GK	-
8	Other				MS

PGLP, phosphoglycolate phosphatase; GOX, glycolate oxidase; GlcDH, glycolate dehydrogenase; CAT, catalase; GGAT, glutamate:glyoxylate aminotransferase; GDC, glycine decarboxylase; SHMT, serine hydroxymethyltransferase; SGAT, serine:glyoxylate aminotransferase; HPR, hydroxypyruvate reductase; GK, glycerate kinase; GlycolateDH, glycolate dehydrogenase; GCL, glyoxylate carboxylase; TSR, tartronic semialdehyde reductase; ME, malic enzyme; PDH, pyruvate dehydrogenase; HPI, hydroxypyruvate isomerase; MS, malate synthase.

Similar to bypass 1, bypass 2 starts with a photorespiratory intermediate and ends with another photorespiratory intermediate (Carvalho et al., 2011; Peterhansel et al., 2013). As well as bypass1, bypass 2 integrates bacterial proteins into plant metabolism to shorten the original photorespiratory pathway. However, these genes are targeted to the peroxisome. Bypass3 is unlike bypass1 and bypass2; its products are not reconnected to the major photorespiratory pathway (Fahnenstich et al., 2008; Maier et al., 2012). Glycolate oxidation is catalyzed by glycolate oxidase that was relocated from the peroxisome to the chloroplast. The H₂O₂ by-product generated during glycolate oxidation is detoxified by the relocated catalase enzyme in the chloroplast. Afterwards, glyoxylate is converted to malate by catalysis of malate synthase in the presence of acetyl-S-CoA. CO₂ release in the chloroplast is started by decarboxylation of malate to pyruvate by malic enzyme (ME). Finally, pyruvate is oxidized to CO₂ by pyruvate dehydrogenase (PDH), and acetyl-S-CoA is produced as a by-product.

1.8. Improvement of cyanide resistance by installing a novel detoxification pathway in *Arabidopsis thaliana*

The previous chapter described the photorespiration process that increased under various abiotic stresses and highlighted different strategies that attempt to manipulate this wasteful process. Another small compound that is generated in higher plants during abiotic stress is cyanide (Liang, 2003) that may cause severe toxicity to plants. Although cyanide is involved in several biochemical pathways, it could be highly toxic at higher concentrations (Yu et al., 2005). Generally, the endogenous cyanide produced under normal conditions is not harmful to plants as it usually found in concentrations under the metabolic capacity (Goudey et al., 1989; Manning, 1988). However, if the endogenous concentrations of cyanide exceed the metabolic capacity of plants, potential toxic effects could be induced that can lead to plant death. For example, treating of barnyard grass (*Echinochloa crus-galli*) with the herbicide quinolinecarboxylic acid (quinclorac) resulted in cyanide concentrations in the shoots by three times higher than the control plants. These levels caused severe symptoms to barnyard plants such as chlorosis, necrosis, loss in the fresh weight and reduction of the shoot growth (Siegień and Bogatek, 2006). The endogenous cyanide concentrations and thus the resulting symptoms were highly correlated with quinclorac concentrations (Siegień and Bogatek, 2006). Beside endogenous cyanide, plants are exposed to cyanide from various exogenous sources. Depending on cyanide concentration, it can function as a nitrogen source or a highly metabolic inhibitor to plants. For example, weeping willow trees (*Salix babylonica L*) grown in hydroponic solution containing low cyanide concentrations ($KCN < \text{or} = 20\mu\text{M}$) had no signs of toxicity, while at higher concentrations ($KCN > \text{or} = 50\mu\text{M}$) severe signs of toxicity were observed (Yu et al., 2005). Moreover, weeping willows grown in sandy soil irrigated with low doses of cyanide ($KCN < \text{or} = 50\mu\text{M}$) survived without any toxic effect the entire experiment time (nine days). However, higher doses of cyanide ($KCN > \text{or} = 300\mu\text{M}$) were lethal for weeping willows after nine days (Yu et al., 2005). In addition, cyanide application has been found to cause noticeable decrease of chlorophyll content in *Arabidopsis* plants when exposed to $50\mu\text{M}$ HCN (McMahon Smith and Arteca, 2000) and necrotic spots on tobacco leaves (Siefert et al., 1995). The toxic effect of cyanide is mostly associated with its ability to form metal complexes with several principle metalloenzymes such as cytochrome c oxidase , superoxide dismutase, peroxidase, catalase and Rubisco (Siegień and Bogatek, 2006).

1.9. Different sources of cyanide

Plants are exposed to cyanide from both natural and manufactured sources. Cyanide is produced naturally in plants as a by-product in the last step of ethylene biosynthesis during several plant growth stages such as germination, root-hair initiation, senescence and abscission, fruit ripening, and the response to various stresses (Goudey et al., 1989). Moreover, several plants have the ability to produce and store cyanide as cyanogenic glycosides including the plant families Rosaceae, Fabaceae, Limaceae, and Compositae (Poulton, 1988). Decomposition of cyanogenic plants might affect other plants in the neighborhood. Furthermore, plants might be influenced by cyanogenic bacteria that colonize the rhizosphere (Gallagher and Manoil, 2001). It has been reported that cyanide concentrations were higher as 100mg kg dw^{-1} in the rhizosphere of some plants colonized by cyanogenic bacteria (Owen and Zdor, 2001).

The major cyanide waste in the environment is coming from human activities. Cyanide is extensively used by industries such as plastics industries, organic chemicals production, photographic development, pharmaceuticals, electroplating, and metal finishing (Patil and Paknikar, 2000). A great amount of cyanide is used in gold and silver mining as a lixiviation to leach these precious metals from the ores. More than 90% of gold extraction is done by cyanidation (Trapp et al., 2003). Cyanide concentrations in soils near the industries that release cyanide can exceed 1000mg kg dw^{-1} , while in wastewater it may be an order of magnitude higher (Henny et al., 1994).

1.10. Bioremediation of cyanide

The widespread usage of cyanide for gold and silver extraction and many other industries imposes a serious ecological risk for ecosystems and mankind. Several disasters associated with cyanide waste have occurred worldwide such as release of methyl isocyanate in the Union Carbide Manufactory in Bhopal December 1984 (Sriramachari and Chandra, 1997), spilling of cyanide at Baia Mare, Romania 2000 (Korte et al., 2000), spilling of cyanide from the Ashanti gold fields in Ghana, and several accidents in China were reported (Yu et al., 2004). Although such accident is rare, it highlights the importance of detoxifying and cleaning cyanide waste. Several studies reported the capability of various micro-organisms including bacteria, fungi and algae to detoxify cyanide pollutant in wastewater of gold and silver mining industry (Naveen et al., 2011). Moreover, all the investigated higher plants including both cyanogenic and non

INTRODUCTION

cyanogenic plants were found to possess one or more enzymes that assimilate cyanide (Miller and Conn, 1980). The uptake, and metabolism of cyanide by higher plants has been investigated (Ebbs et al., 2003; Larsen et al., 2005). However, tolerance and assimilation of higher plants to cyanide is highly depending on its metabolic capacity as described previously (See 1.9). Although, several chemical and physical methods have been established for cyanide detoxification, these methods tend to be complex and expensive processes (Akcil, 2003). Biological degradation of cyanide can be an alternative solution (Akcil and Mudder, 2003). Introducing novel genes into plant genome by genetic engineering techniques may enhance its degradation capacity to cyanide. Consequently, the transgenic approaches can provide an efficient, cheap and environment-friendly method for cyanide degradation.

There are several enzymes have already been reported to detoxify cyanide from various organisms including all phyla. For instance, β -cyanoalanine synthase enzyme that is localized in the mitochondria of higher plants and is believed to have a principle role in detoxifying the endogenous cyanide (Yu et al., 2012). The enzyme catalyzes the substitution of a thiol in cysteine with cyanide producing β -cyanoalanine that is then converted to asparagines by nitrile hydratase. Radioactive studies revealed the principle role of β -cyanoalanine synthase in incorporating the exogenous cyanide into the amino acids pools in higher plants (Peiser et al., 1984). The reaction is shown in equation 1.

In bacteria, another type of enzymes was reported for cyanide detoxification known as cyanidases (Ingvorsen et al., 1991; Jandhyala et al., 2003). Cyanidases catalyze conversion of cyanide directly to formate and ammonia. The reaction is shown in equation 2.

1.11. The aim of the present study

In the framework of this study, there were two main goals: the first main goal was the biochemical characterization of a putative glycolate dehydrogenase enzyme from *Chlamydomonas reinhardtii* (CrGlcDH). Moreover, in order to better understand the importance of the Fe-S conserved domain for the activity of CrGlcDH enzyme, different mutations were performed. Furthermore, the evolution of CrGlcDH enzyme was explored *in silico* through analysis of the phylogenetic relationships, and studying the enzymatic properties of one of the nearest homologous sequences. These analyses should provide a basis for the optimization of the photorespiratory bypass reported by Kebeish et al (2007). Such approaches should reduce abiotic stress in higher plants.

The second main goal was to establish a novel method for bioremediation of cyanide toxicity using transgenic *Arabidopsis thaliana* as a model plant. Two functional transgenes (a cyanidase gene originated from bacteria and a formate dehydrogenase gene from *Arabidopsis thaliana*) were characterized and cloned into plant expression vectors. Afterwards, the two transgenes were transferred to the nuclear genome of wild type *Arabidopsis thaliana* plants through *Agrobacterium* mediated genetic transformation. Under cyanide stress, the combination of both transgenes should result in enhanced levels of CO₂ and ammonia that will be fixed by the chloroplastic enzymes and integrated in the basal plant metabolism as a source for carbon and nitrogen, respectively. This approach should also result in a reduction of photorespiration. Molecular, physiological, and biochemical studies were performed in order to ensure the success of implementing the method proposed in this study.

MATERIALS AND METHODS

2. Materials and methods

2.1. Materials

2.1.1. Plant materials

Arabidopsis thaliana ecotype Columbia plants were used to generate stable expression lines of cyanidase and formate dehydrogenase.

2.1.2. Bacterial strains

Table 2. Bacterial strains used throughout this study.

Bacterial Strain	Features	Antibiotic resistance	Purpose
DH5 α	It has recA1 and endA1 mutations that increase insert stability and improve the quality of plasmid DNA prepared from minipreps.		Plasmid - miniprep
XL1-Blue	This strain has recA1 and endA1 mutations which greatly improves the quality of miniprep DNA. The hsdR mutation prevents the cleavage of cloned DNA by the EcoK endonuclease system. The lacIq Δ M15 gene on the F' episome allows blue-white screening for recombinant plasmids.	Tetracycline (12.5 μ g/ml)	Plasmid – miniprep
BL21(DE3)	DE3 lysogen contains T7 polymerase suitable for IPTG induction. This strain is deficient of lon and omp-t proteases and is therefore suitable for expression of non-toxic genes.		Protein expression
BL21 codon Plus	BL21 codon plus strain is recommended for expressing heterologous protein with codon bias. This strain possesses extra copies of the argU, ileY, and leuW tRNA genes. The tRNAs encoded by these genes recognize the AGA/AGG (arginine), AUA (isoleucine), and CUA (leucine) codons, Respectively.	Tetracycline (12.5ug/ml) Chloramphenicol (34ug/ml)	Protein expression
C41(DE3)	This strain is effective in expressing toxic and membrane proteins. It was derived from BL21 (DE3), and has at least one uncharacterized mutation that prevents cell death associated		Protein expression

MATERIALS AND METHODS

	with expression of many toxic recombinant proteins.		
C43(DE3)	Similar to C41 (DE3), this strain is recommended for expressing toxic and membrane proteins.		Protein expression
Rosetta gami-pLysS	Rosetta-gami strains are suitable for expression of eukaryotic proteins that contain codons rarely used in <i>E. coli</i> . These strains supply tRNAs for AGG, AGA, AUA, CUA, CCC, GGA on a compatible chloramphenicol resistant plasmid. In addition, this strain enhances the disulfide bond formation resulting from <i>trxB/gor</i> mutations.	Kanamycin (25ug/ml) Tetracycline (12.5ug/ml) Chloramphenicol (34ug/ml)	Protein expression
ER2566	<i>E. coli</i> B cells engineered to form proteins containing disulfide bonds in the cytoplasm. Suitable for T7 promoter driven protein expression.		Protein expression
<i>Agrobacterium</i> strain GV3101 (pMP90RK)	This <i>Agrobacterium</i> strain contains a Ti plasmid pMP90RK that represents one component of the binary vector system. This plasmid contains the <i>vir</i> -region as well as the genes for gentamycin and kanamycin resistances. This bacterial strain is used for delivering heterologous genes to tobacco and <i>Arabidopsis</i> plants.	Gentamycin (50µg/ml) Kanamycin (50µg/ml) Rifampicin. (50µg/ml).	Plant transformation

2.1.3. Chemicals and consumables

The chemicals were purchased from the following companies: Amersham Pharmacia Biotech (Freiburg), AppliChem (Darmstadt), BioRad Laboratories GmbH (München), Boehringer Roche (Mannheim), Calbiochem (Bad Soden), Carl Roth GmbH (Karlsruhe), Gibco BRL (Eggenstein), Hartmann Analytic (Braunschweig), Invitex (Berlin), Invitrogen (Leck, Netherlands), KMF Laborchemie Handels GmbH (St. Augustin), Kodak (Stuttgart), Life Technologies (Carlsbad, United States of America), Merck (Darmstadt), Metabion (Martinsried), Molbiol (Hamburg), New England Biolabs (Frankfurt), Peglab (Erlangen), Pharmacia (Freiburg), Promega (Madison, United States of America), Thermo Scientific Fermentas (St.- Leon-Rot), QIAGEN (Hilden), Roche Diagnostic GmbH (Mannheim), Serva (Heidelberg), Sigma-Aldrich (Taufkirchen), VWR (Darmstadt), Worthington (Lakewood, New Jersey, United States of America).

The consumables were obtained from: Applied Biosystems (Darmstadt), Beckman Coulter (Fullerton, United States of America), Biometra (Göttingen), BioRas Laboratories GmbH (München), Eppendorf (Hamburg), Fuji (Düsseldorf), Gibco BRL (Eggenstein), Greiner (Solingen), Hanna Instruments (Kehl), Heraeus (Osterode), Herolab (Wiesloch), Hettich Zentrifugen (Tuttlingen), Kodak (Stuttgart), Labomedic (Bonn), LI-COR® Biosciences (Lincoln, United States of America), Merck (Darmstadt), Millipore (Eschborn), MWG Biotech (München), Pharmacia (Freiburg), Raytest (Berlin), Serva (Heidelberg), Schott Glaswerke (Mainz), Sorvall (Bad Homburg), Wissenschaftliche Technische Werkstätten (Weilheim), Whatman (Maidstone, Kingdom of Great Britain), Zinsser Analytic (Frankfurt).

2.1.4. Instruments and equipment

Table 3. Instruments and equipment used in this study.

Instruments/Equipment	Company

MATERIALS AND METHODS

2.1.12. Plasmids

Table 10. List of plasmids generated in course of this study.

No.	Construct name	Usage
1	pTRA-K-TL- ctp-CYND-His	Chloroplastic expression of cyanidase (CYND) enzyme.
2	pTRA-K-TL-FDH	Cytosolic expression of formate dehydrogenase (FDH) enzyme.
3	pTRA-K-ctp-FDH-CYND-His	Chloroplastic expression of both FDH and CYND genes enzyme.
4	pET22- <i>CrGlcDH</i> -His	Bacterial expression of <i>CrGlcDH</i> enzyme.
5	pET22-mut1- <i>CrGlcDH</i> -His	Bacterial expression of mutant1 of <i>CrGlcDH</i> enzyme.
6	pET22-mut2- <i>CrGlcDH</i> -His	Bacterial expression of mutant2 of <i>CrGlcDH</i> enzyme.
7	pET22-delta- <i>CrGlcDH</i> -His	Bacterial expression of delta <i>CrGlcDH</i>
8	pET22- <i>DvDLDH</i> -His	Bacterial expression of <i>DvDLDH</i> enzyme.
9	pET41- GST- <i>CrGlcDH</i> -His	Bacterial expression of <i>CrGlcDH</i> with GST fusion tag.
10	pMAL- <i>CrGlcDH</i>	Bacterial expression of <i>CrGlcDH</i> with maltose binding fusion tag.

MATERIALS AND METHODS

Figure 8. Structure of different plasmids constructed during this study. A, pET22-His plasmid that was used for expression of *CrGlcDH* protein and its mutants with His-tag fusion at C-terminal. B, pET22-*DvDLDH*-His plasmid was used for expressing of β -Lactate dehydrogenase from *Desulfovibrio vulgaris* with His-tag fusion at C-terminal. C, pMAL-*CrGlcDH* plasmid was used for expression of *CrGlcDH* protein with maltose binding fusion tag. D, pET41-GST-His plasmid was used for expressing of *CrGlcDH* with a glutathione-S-transferase fusion tag at N-terminal and His-tag at C-terminal. And E, pTRA-K-CTP-FDH-CYND-his plant expression vector, was used for expressing of cyanidase protein in the chloroplast of *Arabidopsis thaliana*.

2.1.13. Software and internet programs

Table 11: Software and internet-programs used throughout this study.

Software/internet-program	Characteristics
ABI Prism® 7300 SDS software 1.4	Software for enforcement and evaluation of ABI Prism® 7300 sequence detection system.
Clone manager professional 9	Nucleic acid sequence analysis.
Mega 5	MEGA software is an integrated tool for conducting sequence alignment, inferring phylogenetic trees, estimating divergence times (Tamura et al., 2011). http://www.megasoftware.net/ .
Multiple sequence alignment by CLASTALW	Internet program for sequence alignment, http://www.genome.jp/tools/clustalw/ .
National centre for biotechnology information (NCBI)	Internet database for sequencing, http://ncbi.nlm.nih.gov/ .
Oligonucleotides properties calculator (OligoCalc)	Internet program for oligonucleotides analyses, http://www.basic.northwestern.edu/biotools/oligocalc.html .
SeqLab	Internet program for sequencing, http://seqlab.de/

2.2. Methods

2.2.1. Molecular methods

2.2.1.1. DNA and RNA extraction (Combined method) from plant material

A frozen and well ground plant material was used for extraction of DNA and RNA in a combined method. 100mg ground plant material was mixed with 500 μ l DNA/RNA extraction buffer (Table 9). Afterwards, 1 volume of water saturated phenol was added and was mixed gently for 10 to 15min on a shaker followed by centrifugation at 16000xg for 10min. The upper phase was transferred to a new tube and 0.1 volumes of 3M NaAc (pH 5.2) and 2 volumes of ethanol (96%) were added and mixed well. The DNA and RNA were precipitated by centrifugation at 16000xg for 10min at 4°C. The aqueous phase was removed and the resulting pellet was washed by adding 300 μ l 70% ethanol. The mixture was centrifuged for 10min (16000xg, 4°C). Finally, the ethanol was completely removed, and the pellet was dissolved in 100 μ l sterile H₂O and stored at -20°C until used.

2.2.1.2. Polymerase chain reaction

The Polymerase chain reaction (PCR) is a powerful amplification technique that can generate a huge amount of a specific segment of DNA (Saiki *et al.*, 1988). Two synthetic oligonucleotides with known sequences designated as primers (a forward and a reverse primer) are required to initialize the amplification process. The target is flanked by the primers, which are complementary to the (+) and (-) strands of the DNA. The new strands are synthesized between the two primers by catalysis of *Taq* DNA polymerase enzyme. Amplification of the DNA fragment is performed by repeating the reaction several cycles. Each cycle contains three main stages: the denaturation, the annealing, and the extension (Lorenz, 2012). Repeating the cycles of denaturation, primer annealing and extension results in an exponential accumulation of the target DNA fragment. See below the reaction composition and conditions used in this study (Table 12&13).

MATERIALS AND METHODS

2.2.1.3. Multiplex PCR

With help of this technique, it is possible to amplify more than one DNA fragment using more than one primer pair in the same PCR reaction mixture (Table 12). In this study this method was used to amplify the actin2 (Plant control) together with the different transgenic constructs. The standard multiplex PCR conditions were used for fragment amplification (Table 13).

Table 12. PCR reaction mixture.

Reagent	Final concentration
Dream- <i>Taq</i> Buffer (10X)	1x
dNTP mix	200 μ M
Forward primer	0.2 μ M
Reverse primer	0.2 μ M
<i>Taq</i> polymerase	0.02 μ M
Template	1 – 2ng/ μ l
H ₂ O	Ad 25 μ l

Table 13. Standard PCR conditions.

Reaction step	Temperature	Duration	Cycle
Initial denaturation	94°C	5min	1x
Denaturation	94°C	30sec	
Annealing	50-60°C ??	30sec	35x
Elongation	72°C	2min ??	
Deactivation	72°C	5min	
Rest	16°C		

2.2.1.4. Purification of PCR products and digested DNA fragments

The MSB Spin PCRapace kit (Invitex, Berlin) was used to purify PCR products and the digested plasmids. The kit was used according to the manufacturer's instruction.

2.2.1.5. Isolation of plasmid DNA

Plasmid DNA mini kits (GeneJet Plasmid Miniprep Kit, Thermo Scientific Fermentas) was used to isolate plasmid DNA. The kit was used according to the manufacturer's instruction.

2.2.1.6. Agarose gel electrophoresis

Agarose gel electrophoresis method enables researchers to separate and visualize DNA fragments. DNA fragments are forced to migrate through an agarose matrix in response to an electric field. Agarose is a polysaccharide that produces cross-linked matrix during its polymerization with a particular size depending on agarose concentration. Therefore, small fragments run more quickly than the bigger fragments through the agarose matrix. All agarose gel electrophoreses for DNA separation was performed as previously published (Sambrook and Russell, 2001). Briefly, 0.8-2% (w/v) agarose was dissolved in 1x TAE buffer (Table 9) by heating in a microwave. Ethidium bromide was added to the melted agarose solution at a relationship of 1:20,000. In order to create pockets inside the gel, the solution was poured in a plastic template with a comb placed inside. After gel solidification, the comb was removed and the DNA samples, mixed with loading buffer, were loaded in the pockets. To enable subsequent size determination of the DNA fragments 5 μ l of the DNA ladder (Invitrogen) was also loaded. The DNA samples were run at 1.5 mA/cm² in 1x TAE buffer. Finally, the separated DNA fragments were visualized on a UV table.

2.2.1.7. Purification of DNA fragments from agarose gels

To purify DNA fragments (70bp - 10kb) from agarose gels, the Invisorb[®] Spin DNA Extraction Kit (Invitek, Berlin) was used according to the manufacturer's instruction.

2.2.1.8. Restriction enzyme digestion

Restriction reactions were performed as described in the manufacturer's instruction.

2.2.1.9. Ligation

Ligation of DNA is performed using DNA ligase enzyme (Thermo Scientific Fermentas, Germany). DNA ligases catalyze the formation of a phosphodiester bond between the 3' hydroxyl and 5' phosphate of adjacent DNA residues. The reaction was performed as described in the manufacturer's instruction, except the incubation step, which was performed over night at 16°C.

2.2.1.10. DNA Sequencing

DNA sequencing was performed by the SeqLab Company. For this purpose, approximately 600-700ng of the required plasmid was mixed with 20pmol of the used primers followed by adding water to a volume of 7µl.

2.2.1.11. cDNA synthesis from RNA

Complementary DNA (cDNA) is catalyzed by the reverse transcriptase enzyme. During this process, DNA is synthesized from the messenger RNA (mRNA). Briefly, the isolated DNA/RNAs samples (See 2.2.1.1) were digested by *DNase* enzyme. The samples were incubated with *DNase* enzyme for 30min at 37°C followed by additional 15min at 70°C. Afterwards, 1µl of the random primer (Table 8, primer no. 41) was added to the samples and incubated for 5min at 75°C followed with cooling on ice. Then, 7µl of the RT-reaction mix (Table 14) was added to each sample. The mixture was incubated for 1h at 37°C. Finally, the enzyme was inactivated by incubation at 70°C for 10min. As control, reaction mixtures without *DNase* enzyme were used. The samples were diluted 1:4 and 1:16 with H₂O before cDNA synthesis. Finally, the resulting cDNA samples were diluted 1:2 and used as templates for gene expression analysis (qPCR).

Table 14. RT reaction mix.

Compound	End concentration
dNTP mix	20nmol
MMLV buffer	1 x
MMLV RT	200u
H ₂ O	7µl

2.2.1.12. Quantitative RT-PCR

RNA was prepared from *Arabidopsis thaliana* leaves following the BCP (1-bromo-3-chloropropane) protocol (Chomczynski and Mackey 1995). Preparation of first strand cDNA was performed as described by Niessen et al. (2007). Quantitative PCRs were performed on an ABI PRISM 7300 Sequence Detection System (Applied Biosystems, Darmstadt, Germany) in the presence of SYBR Green following the manufacturer's instructions. Reaction mix was obtained from Invitrogen, Karlsruhe, Germany, and oligonucleotides were purchased from Metabion, Planegg, Germany. For the detection of FDH transcripts, primers 5'-GCT GTT GTT GAT GCT GTT GAA-3' and 5'-TCC TTA GGA GCT GGT TGT GG-3' were used. For the detection of CYND transcripts, primers 5'-GCC TAA CCC AGT TGT CAG AAA-3' and 5'-GCA AGG AAC GCA CTA CTG G-3' were used. For the detection of Actin2 transcripts, primers 5'-GGT AAC ATT GTG CTC AGT GGT GG-3' and 5'-GGT GCA ACG ACC TTA ATC TTC AT-3' were used. The final primer concentration was 200nM in the reaction mixture. Amplification conditions were 10 min of initial denaturation at 95°C, followed by 40 cycles each of 15s denaturation at 95°C and 1min combined annealing and extension at 60°C.

2.2.1.13. Phylogenetic tree assembly

Amino acid sequences from bacteria, fungi, algae and plants were obtained from the NCBI databases using a combination of queries based on key terms and BlastP searches (Altschul *et al.*, 1997). Protein sequence alignments were performed with MEGA5.1 software (Tamura *et al.*, 2011). Phylogenetic analyses were inferred in MEGA5.1 using neighbor joining (NJ) method. The NJ tree was constructed from pairwise amino acid distances estimated using a Poisson correction and different rates among sites (gamma distributed). Bootstrap values (%) are for 500 replicates. *Arabidopsis* GOX was used as an outgroup.

2.2.2. Biochemical methods

2.2.2.1. Protein extraction from plant leaves

Frozen leaves were finely ground in liquid nitrogen. Approximately 150mg ground leaf material was placed in 1.5ml eppendorf tube and mixed with 700µl of protein extraction buffer (Table 9) followed by centrifugation (30000xg/15min/4°C). The supernatant was transferred into a new

MATERIALS AND METHODS

1.5ml eppendorf tube and centrifuged once more to remove any remaining debris. Finally, the supernatant was transferred into clean eppendorf tube and placed in ice. Protein concentration was measured using Bradford solution.

2.2.2.2. Determination of protein concentrations

Proteins concentrations were determined according to the method described by (Bradford, 1976). From protein samples 2 μ l was mixed with 1ml of Bradford reagent (Table 9) and incubated for 5 min at room temperature (RT). The extinction at 595nm was measured against a reagent blank prepared from 2 μ l of the corresponding extraction buffer and 1ml of Bradford reagent. Different concentrations of bovine serum albumin protein (pH 7.0, Serva) were used to prepare a standard curve in a range between 1 and 20 μ g.

2.2.2.3. Expression and Purification of recombinant proteins

A single colony of *E. coli* strain harboring the gene of interest was inoculated in 5ml of LB medium containing the appropriate antibiotics and cultivated ON at 37°C. On the second day, the ON culture was transferred into 1000ml LB + antibiotics and left to grow until OD_{600nm} of 0.9. Protein expression was induced by addition of IPTG to a final concentration of 1mM for 2hr. The culture was centrifuged (4000xg/4°C/10min) and bacterial pellets were immediately frozen with liquid nitrogen and were kept in -80 freezer. The bugbuster master mix (Novagen) was used for protein extraction. The His-tagged recombinant protein was purified by Ni²⁺-NTA resin (Qiagen). The purification was performed according to the manufacture's instruction with some modifications. The binding step was performed in batch using 15ml falcon tube for 1h at 4°C. Afterwards, the resin was carefully transferred into 1.5ml eppendorf

tube. The non-specifically bound proteins were removed by washing with 5 resin volume of protein-wash-buffer. Finally, the recombinant protein was eluted using 3x 100 μ l of protein elution buffer. All the purification steps were performed at 4°C. The centrifugation steps were performed at 1000xg.

2.2.2.4. SDS-polyacrylamide gel electrophoresis

The size-dependent separation of denatured protein was performed according to (Laemmli, 1970). The polyacrylamide gels required for this purpose were cast in a mini gel system (The

MATERIALS AND METHODS

Bio-Rad min protein II apparatus). After gel preparation, each protein sample was mixed with 5x SDS-PAGE-samples buffer (Table 9), boiled at 95°C for 5min, and spun down for 30sec. The boiled sample was then loaded into polyacrylamide gel (Ausubel et al., 2001). To be able to estimate the protein size, pre-stained molecular weight markers were used (Thermo Scientific Fermentas). 1x SDS-PAGE electrophoresis buffer (Table 9) was used for the electrophoresis that was performed for 120min at 120V/cm. Separated proteins were visualized by gel staining with Coomassie brilliant blue R250 (Table 9) or transferred onto a nitrocellulose membrane for western blotting analysis (Table 9).

2.2.2.5. Coomassie brilliant blue staining

Although, the presence of around 40 dyes called CoomassieTM xy, only CoomassieTM G250 and CoomassieTM R250 play a crucial role in biochemical analyses. Coomassie Brilliant Blue R-250 was first used to stain proteins in a polyacrylamide gel by (Meyer and Lamberts, 1965). CoomassieTM Brilliant Blue forms strong but non-covalent complexes with proteins, most probably based on a combination of van der Waals forces and electrostatic interactions. Formation of the protein/dye complex stabilizes the negatively charged anionic form of the dye producing the blue color in the gel.

The polyacrylamide gel containing the separated protein was placed carefully in coomassie dye solution (Table 9) and stained for 30min at RT while shaking gently. Non-specific background staining was removed using coomassie-destaining solution (Table 9) overnight at RT.

2.2.2.6. Western blot

Transfer of the electrophoretically separated proteins from polyacrylamide gels onto a HybondTM-ECLTM-nitrocellulose membrane (0.45µm) was achieved using a tank-blotting transfer chamber (Biorad). The tank-blotting western blot was performed according to qiaexpress detection and assay handbook (Qiagen, Hilden, Germany). Briefly, a nitrocellulose membrane was cut according to the gel size and soaked in the tank-blotting transfer buffer for some minutes (Table 9). The gel was placed in between a sandwich-like structure of two filter papers and two fiber pads as shown in figure 9. The air bubbles between the gel and the membrane were carefully removed. The sandwich-like structure was hold with a plastic supporter. The tank was filled with transfer buffer and protein transfer was performed at 250mA for 1h. Afterwards, the

MATERIALS AND METHODS

membrane was washed two times 10min each with TBS buffer (Table 9) at RT then incubated 1h in blocking buffer (Table 9) at 4°C. The blocked membrane was washed 2 times 10min each at RT with TBS-Tween/Triton buffer (Table 9) followed by two times with TBS buffer for 10min each then incubated in Anti-His HRP conjugate solution (Qiagen, Hilden, Germany) containing 1/2000-1/1000 dilution of antibody in blocking buffer (Qiagen, Hilden, Germany) at RT for 1h. Finally, the membrane was washed 2 times with TBS-Tween/Triton buffer (Table 9) followed by 2 times 10min each with TBS buffer (Table 9). The signals were visualized by adding lumi-light western blotting substrate (Lumi-light stable peroxide solution : lumi-light luminol/enhancer solution = 1:1 from Roche Diagnostics GmbH, Mannheim, Germany) to the membrane and incubated in dark for 5min then luminescence was recorded on a LAS3000 CCD camera (Raytest) according to the manufacturer's recommendations.

Figure 9. Schematic drawing of indicated tank- blotting methods. Arrow shows direction of the transfer (Qiagen Handbook).

2.2.2.7. Truncated protein version and site-directed mutagenesis

Oligonucleotides 5'-TAT GCC ATG GGC GCG AGA GGT CCT GCA TCT-3' as forward primer and 5'- GAT GCT CGA GGA ACT TGA TGT GAG CGT CCT GAT CT-3' as reverse primer were used to amplify a truncated version (660aa from the N-terminus) of *CrGlcDH*. Site-directed mutagenesis was performed with the lightning quick-change site-directed mutagenesis kit (Agilent Technologies, Boeblingen, Germany) following the manufacturer's instructions to change cysteine 673, 676, 679 and 683 to serine. Synthetic oligonucleotide primers were 5'-

MATERIALS AND METHODS

CAGATGTATCGAGAGCGGATTCAGCGAG-TCTAACAGTCCATCA-3' for mut1 and 5'-CAGAAGTATCGAGAGCGGATTCAGCGAG-TCTAACAGTCCATCA-3' for mut2. The reverse primer was 5'-TGATGGACTGTTAGA-CTCGCTGAATCCGCTCTCGATACTTCTG-3'. Constructs were amplified in *E. coli* XL10-Gold ultracompetent cells provided with the kit and screened using primers 5'-TAGCGCAGCTGATGGAATGAGCCAAGAGAAGAGTCCA-3' as forward primer and 5'-GACTCTTCTCTTGGCTCATTCCATCAGCTGCGCTAG-3' as reverse primer. Positive constructs were sequenced by SeqLab (Goettingen, Germany). Expression and purification conditions were as described above (See 2.2.2.3).

2.2.2.8. Enzymatic activity assays

Enzymatic activity was assayed according to (Lord, 1972) with few modifications. Bacterial cell extract containing 100 μ g of total protein or 0.5 μ g of the purified protein was added to 100 μ M Na-phosphate buffer (pH 8.0), 50 μ M 2,6-dichlorophenolindophenol (DCIP), 3mM phenazine methosulfate (PMS), and 10mM glycolate or D/L-lactate in a final volume of 0.2mL. At fixed time intervals, individual assays were terminated by the addition of 8 μ L 32% HCl. After standing for 10min, 42 μ l of 0.1M phenylhydrazine-HCl was added. The mixture was allowed to stand for a further 10min, and then the extinction due to the formation of glyoxylate-phenylhydrazone or pyruvate-phenylhydrazone, respectively, was measured at 324nm.

For testing substrate specificity, enzymatic activity was tested spectrophotometrically with a different assay. Reaction mixture contained 50mM Na-phosphate buffer (pH 8.0), 3mM PMS, 200 μ M DCIP, and 10mM of the tested substrate in a final volume of 0.2ml. Activities were measured at RT ~ 21°C by recording the reduction of DCIP at 600nm (ϵ , 22 cm⁻¹ mM⁻¹).

Cytochrome c reduction was tested in the same buffer containing 50mM Na-phosphate buffer pH 8.0, 10mM glycolate/D-Lactate and 200 μ M equine cytochrome c (Sigma, Taufkirchen, Germany) instead of DCIP. OD change was measured at 550nm (ϵ , 18.6 cm⁻¹ mM⁻¹). The resulting activity was divided by two since two moles of cytochrome c are reduced for each mole of substrate oxidized.

2.2.3. Biological methods

2.2.3.1. Culture of bacteria

I) *Escherichia coli*

Different *E. coli* strains (Table 2) were cultured in Luria-Bertani (LB) rich medium (Bertani, 2004). The bacteria were grown at 37°C.

II) *Agrobacterium tumefaciens*

Agrobacterium tumefaciens bacteria were cultured in YEB medium Broth (Table 9) that is based on the formula described by (Song et al., 2004). The bacteria were grown at 28°C.

2.2.3.2. Preparation of competent *E. coli* cells for heat shock transformation

From a fresh *E. coli* culture a single colony was inoculated into 5ml LB medium and incubated ON at 37°C with continuous shaking (200xg). On the second day, the ON culture was used to inoculate fresh 200ml LB medium and the culture was left to grow at the same conditions until the OD_{600nm} reached 0.5 - 0.6. Afterwards, bacterial culture was spun down for 10min (4000xg/4°C) and the pellet was then resuspended with 15ml ice-cold TFBI buffer (Table 9) and left in ice for 10min. The bacterial cells were centrifuged and the pellet was resuspended in 4ml TFBII buffer (Table 9). Finally, aliquots of 200µl of the suspension were dispensed into pre-chilled Eppendorf tubes, and were immediately frozen in liquid nitrogen and stored at -80°C.

2.2.3.3. Transformation of competent bacteria by heat-shock

The competent *E. coli* cells prepared as shown previously (See 2.2.3.2) were defrosted in ice before using. Plasmid DNA (10-100ng) or the ligation products (1-3µl) were added to the competent cells and gently mixed and incubated in ice for 30min. Afterwards, the cells were heat-shocked (45sec at 42°C), and were immediately rested in ice. The transformed cells were recovered by adding 1ml of LB medium without antibiotics and were incubated at 37°C for 60min with continuous shaking (180xg). Different volumes: 50, 100 and 150µl of the transformed cells were placed on LB-agar plates supplemented with appropriate antibiotics (Table 4) and incubated at 37°C ON.

2.2.3.4. Preparation of competent *Agrobacterium* cells for electroporation

From a fresh culture of *Agrobacterium tumefaciens* grown on YEB-agar plates containing 100µg/ml rifampicin (Rif) and 25µg/ml kanamycin (Kan) (YEB+Rif+Kan), a single colony was used to inoculate 5ml of YEB+Rif+Kan medium and incubated at 28°C for two days with shaking (200xg). Afterwards, 1ml of the culture was transferred into 200ml fresh YEB+Rif+Kan medium and the culture was left to grow until the OD_{660nm} reached 1-1.5. Then, cells were centrifuged (4000xg/4°C/10min) and the bacterial pellet was washed three times with 100ml, 50ml and 25ml cold HEPES buffer I (Table 9), respectively, and one time with 10ml HEPES buffer II (Table 9). Finally, the cells were resuspended in 500µl of sterile HEPES buffer II (Table 9) and aliquots of 45µl were dispensed into pre-chilled Eppendorf tubes, frozen immediately in liquid nitrogen and stored at -80°C.

2.2.3.5. Transformation of *Agrobacterium tumefaciens* by electroporation

The competent *A. tumefaciens* cells (See 2.2.3.4) were defrosted before using. The plasmid DNA (0.2-1.0µg) was added to the *Agrobacteria* and left in ice for 5min. The mixture was transferred into an electroporation cuvette and exposed to the electric pulse (25 F/2.5 kV/200). The cells then were diluted with 1ml of YEB medium without antibiotics and incubated at 28°C with shaking (200xg) for 60min. Finally, 50µl and 100µl of the transformed cells were placed on YEB plates containing Rif+Kan and the antibiotic suitable to the plasmid. The plates were incubated at 28°C for 3-4 days.

2.2.3.6. Plant culture, generation and characterization of transgenic plants

Transformation of *Arabidopsis* plants was performed through *Agrobacterium*-mediated floral dip transformation.

I) Preparation of *Agrobacterium*

A pre-culture of *Agrobacterium tumefaciens* carrying the gene of interest was prepared by inoculating a single colony into 5ml YEB medium (100µg/ml Rif+25µg/ml Kan+ 100µg/ml carbenicillin) and incubated at 28°C for 2 days with shaking at 150xg. Afterwards, the pre-culture was transferred into fresh 200ml YEB medium (100µg/ml Rif+25µg/ml Kan+ 100µg/ml carbenicillin) and incubated for additional 2 days at 28°C with shaking at 200xg. The bacterial

MATERIALS AND METHODS

cells were spun down (4000xg /4°C/20min), and the bacterial pellet was resuspended in 5% sucrose until $OD_{600nm} \sim 0.8$. Finally, 0.04 % silwet 1-77 (400 μ l/1000ml) was added to the resuspended and was used directly for floral dip transformation of *Arabidopsis* plants.

II) Transformation of *Arabidopsis* plants (floral dip transformation)

The floral dip transformation of *Arabidopsis* plants was performed as described by (Clough and Bent, 1998). Briefly, the *Arabidopsis* plants were grown under short day conditions (8h/16h, 22/20°C, day/night) to produce biomass. Afterwards, the plants were transferred to a long day conditions (16h light and 8h dark at 23-25°C) to enhance flowering. Bacterial cultures of *Agrobacterium* harboring plasmid with CYND or CYND and FDH together were prepared. The flowers were dipped in the *Agrobacterium* solution for 3 to 10min (Figure 10). The dipped plants were covered ON (16h) in order to maintain humidity. The plants were then transferred to normal growth conditions (16h light and 8h dark at 23-25°C) until plant maturation and seeds harvesting.

III) Selection of the transgenic plants

Selection of transgenic lines was performed on MS+Kan plates as described by (Clough and Bent, 1998). The harvested seeds were sterilized using 98% (v/v) ethanol for 15min then washed three times with 75% (v/v) ethanol, and then the seeds were left to dry. The seeds were placed on MS+Kn plates and left to grow in short day conditions (16h light and 8h dark at 23-25°C) for 10-15 days. The survived plants were transferred to soil. The transgenic plants were confirmed by PCR (See 2.2.1.2) using specific primer. The positive plants were continued growing for seeds production.

Figure 10. Floral dip *Agrobacterium* mediated transformation of wild type *Arabidopsis* plants.

2.2.3.7. Growth assay conditions

Three different systems were used for growth assays under cyanide stress. For determination of root growth in seedlings, plants were grown on vertical MS medium agar plates with or without 250 μ M KCN (plate assay). For determination of rosette size, and fresh weight plants were grown in a hydroponic system in MS medium under short day conditions (8h/16h, 22/20°C, day/night). After two weeks, plants were treated with MS supplemented with 50 μ M KCN for another two weeks (hydroponic assay). Alternatively, plants were grown in sand and watered with MS medium. After four weeks, plants were treated with MS supplemented with 300 μ M KCN for another two weeks in 3-day intervals (Sand assay).

2.2.3.8. Gas exchange measurements

Plants grown in sand and watered with MS+300 μ M KCN for two weeks (Sand assay, see 2.2.3.7.) were used for gas exchange measurements using the LI-6400 system (Li-Cor, Lincoln, NE). Parameters were calculated with the software supplied by the manufacturer. Measuring conditions were photon flux density = 1000 μ mol m⁻² s⁻¹, chamber temperature = 26°C, flow rate = 100 μ mol s⁻¹, relative humidity = 60–70%, and CO₂ = 400ppm. Plant leaves were allowed to adapt for 20–30min to the measuring chamber before each measurement.

3. Results

3.1. Enzymatic characterization of *Chlamydomonas reinhardtii* glycolate dehydrogenase and its nearest proteobacterial homologue

A mitochondrial glycolate dehydrogenase (*CrGlcDH*) in *Chlamydomonas reinhardtii* was initially described by (Nakamura et al. (2005)). Although *CrGlcDH* was reported to encode a GlcDH based on its homology to GlcD and GlcF from *E. coli* (Nakamura *et al.*, 2005), the enzymatic properties of this enzyme were not identified. In order to investigate whether the *CrGlcDH* gene product is a true glycolate dehydrogenase and to determine whether it can be used for the chloroplastic bypass (Figure 6), biochemical characterization of the enzyme was undertaken in this study.

3.1.1. Phylogenetic analysis

A phylogenetic analysis was conducted for *CrGlcDH* gene to get better understanding of the distribution of its orthologous sequences. The *CrGlcDH* amino acid sequence was used for a basic alignment search (BLAST) in the NCBI databank. Representative sequences from bacteria, archaea, chlorophyta and other eukaryotes were selected and used to construct a phylogenetic tree through the neighbor joining method (Figure 11). Arabidopsis GOX (gi|25083945) gene was used as an outgroup for rooting of the phylogenetic tree. The nearest homologues to *CrGlcDH* were found in sequenced genomes of other chlorophytes. All available genome sequences of this clade contained sequences homologous to *CrGlcDH* (data not shown). Surprisingly, the sister-group to the chlorophyta enzymes was made up from proteobacterial enzymes. The selected species represent the subclades alpha (*Azospirillum*), beta (*Dechloromonas*), gamma (*Pseudomonas*), delta (*Desulfovibrio*) and epsilon (*Arcobacter*). However, we did not identify a *CrGlcDH* homologue in the *E. coli* genome (gammaproteobacteria). All the identified *CrGlcDH* homologues in proteobacteria contained homology domains to both GlcD and GlcF over the full length of the protein sequence (Figure 12). Proteins with homology to *E. coli* GlcD, but not GlcF were clustered in a separate clade. This clade contained sequences from different groups of prokaryotes including archaea and cyanobacteria. Many of the proteobacteria that contained a *CrGlcDH* homologue (see above), in addition, were found to contain a GlcD homologue. Putative D-lactate dehydrogenases from different evolutionary groups including ascomycetes (*Saccharomyces*), amebozoza (*Dictyostelium*), and plants (*Arabidopsis*, *Physcomitrella*) formed

RESULTS

a sister group to the GlcD-homologues. Thus, *CrGlcDH* represents a group of proteins found in chlorophyta and some proteobacteria that is evolutionary separated from other GlcD homologues.

Figure 11. Evolutionary relationship of *CrGlcDH* using neighbor-joining method. Bootstrap values (%) are for 500 replicates. Evolutionary distances were computed using the p-distance method. Sequence alignment and evolutionary analyses were conducted in MEGA5.1 software (See 2.2.1.13). *Arabidopsis* GOX was used as an outgroup. Numbers in parentheses are Genbank accession numbers.

3.1.2. Alignment of *CrGlcDH* to its closest proteobacterial sequence

The *CrGlcDH* amino acid sequence was aligned to the nearest proteobacterial *Desulfovibrio vulgaris* (*DvDLDH*, gi|218887286) protein. It was found that the similarity extended over the full length covering the GlcD and GlcF domains. Thus, both proteins might share similar enzymatic characteristics (Figure 12).

RESULTS

3.1.3. Cloning, heterologous expression and purification of *CrGlcDH*

To optimize expression of the recombinant *CrGlcDH* protein, significant efforts were invested during this study. The *CrGlcDH* gene was cloned into several expression plasmids: pET22 with C-terminal 6-histidine fusion tag, pET41 with N-terminal glutathione S-transferase (GST) fusion tag and C-terminal 6-histidine fusion tag, and pMAL with N-terminal maltose binding protein fusion tag. The bacterial strain *E. coli* BL21 codon plus was used to analyze the expression level of the different constructs. In all constructs, the majority of *CrGlcDH* protein was found to accumulate as inclusion bodies, and only a small amount was detected in the soluble fraction by western blotting (data not shown). The construct pET22-*CrGlcDH* with the short histidine fusion tag was used for further investigations. Moreover, several *E. coli* strains: ER2566, BL21 codon plus, Rosette gami, C41 and C43, were used to analyze expression of the recombinant *CrGlcDH* protein. Among the tested bacterial strains, *E. coli* BL21 codon plus was selected for further investigations as it showed the best expression level of *CrGlcDH* in soluble form (data not shown). Further optimization for expression of recombinant *CrGlcDH* in BL21 codon plus was undertaken: expression at different temperatures (4, 17, 25, 30 and 37°C), induction of the expression at different bacterial densities OD_{600nm} (0.6, 0.9, 1.5 and 2), induction of the expression with different IPTG concentrations (0.05, 0.1, 0.5, 1 and 2mM) (data not shown) and induction for different time points (1, 2, 3, 4, 5, 6 hours and ON). Eventually, the expression conditions: grown in LB medium, protein induction at 37°C for 2h by 1mM IPTG were routinely used for *CrGlcDH* expression in *BL21* codon plus. The soluble *CrGlcDH* protein was purified by Ni²⁺-NTA chromatography (Qiagen). The purification was performed according to the manufacturer's instructions with some modifications (See 2.2.2.3). The purified *CrGlcDH* protein was analyzed by SDS-PAGE (See 2.2.2.4) and western-blotting (See 2.2.2.6). A protein of the expected size and two additional protein bands were observed in the eluate (Figure 13). Blotting the purified proteins against anti-His antibodies resulted in two signals: one matched the full-length *CrGlcDH* protein size and the other matched the smallest band of the two contaminating bands (Figure 13). I speculated that the contaminations were derived from *CrGlcDH* protein that was degraded during purification. All the three eluted bands were analyzed by mass spectrometry (Mass spectrometry was done at the Institute of Plant Genetics, Leibniz University Hannover). As expected, all three bands contained peptides derived from *CrGlcDH* (See 6.1, S2).

RESULTS

Figure 13. Purification of *CrGlcDH-His* using Ni^{2+} -NTA affinity chromatography. A, Coomassie stained SDS-PAGE of the progress of recombinant *CrGlcDH* purification. Lane 3, 20 µg of soluble protein extract after IPTG induction from bacteria transformed with the *CrGlcDH-His* construct. Lane 4, 20 µg flow-through fraction. Lane 5-6, washing fractions. Lane 7, 5 µg of purified *CrGlcDH-His* protein.

3.1.4. Cloning, heterologous expression, purification of β -LDH from *Desulfovibrio vulgaris*

In order to compare the catalytic properties of *CrGlcDH* protein with *DvDLDH* protein, the gene was isolated and cloned into pET22 vector (See 6.1, S1 and figure 8). After confirming the sequence, the construct was transformed into *E. coli* BL21 codon plus and was overexpressed using the same conditions that were previously determined for *CrGlcDH* (See 2.2.2.3). Although, the expression was as low as for *CrGlcDH* protein, the soluble protein was purified as described with *CrGlcDH* protein. The eluate fraction was analyzed with SDS followed by western blot (Figure 14). As expected, a signal was detected at molecular weight of 100kDa.

RESULTS

Figure 14. Purification of *DvDLDH-His* using Ni^{2+} -NTA affinity chromatography. A, Coomassie stained SDS-PAGE of the progress of recombinant *DvDLDH* purification. 3.1.5. Screening of the substrate specificity of recombinant *CrGlcDH*

Other GlcDH homologues have been shown to accept wide range of substrates such as glycolate and D -lactate. However the activity of the purified *CrGlcDH* enzyme was tested spectrophotometrically against various substrates by recording the reduction of DCIP at 600 nm (ϵ , 22 $\text{cm}^{-1} \text{mM}^{-1}$) as was described in (See 2.2.2.8). The highest activity was detected with D -lactate. Therefore, the activity with D -lactate was set to 100% (Table 15). Slightly lower activity was observed with glycolate. Moreover, activities with L -lactate and succinate were around 10% compared to D -lactate, and only very low activities were observed with glyoxylate and glycerate as substrates. The other tested short-chain organic acids were not accepted as substrates.

Table 15. Substrate specificity of recombinant *CrGlcDH*. Activity was measured under standard assay conditions described in experimental procedures. Activity with D -lactate as a substrate ($1.0 \pm 0.06 \mu\text{mol min}^{-1} \text{mg}^{-1}$) was set to 100%. Parameters represent mean \pm SE of three independent enzyme preparations.

Substrate	Relative specific activity (% of D -lactate)
No substrate	0.0 ± 0.03
Glycolate	72 ± 1.3
L -lactate	12.5 ± 0.016

RESULTS

D -lactate	100.0 ± 0.0
Formate	0.0 ± 0
Malate	0.0 ± 0
Succinate	8.5 ± 0.001
Acetate	0.06 ± 0.03
Glycerate phosphate	2.8 ± 0.013
Glyoxylate	1.8 ± 0.01
Pyruvate	0.0 ± 0.001

4.1.6. Substrate specificity of *Dv*DLDH

The substrate specificity of *Dv*DLDH was determined using purified protein. The activity was measured with glycolate and D -lactate as substrates as described by Lord (1971) (See methods 2.2.2.8). *Dv*DLDH protein showed activity with D -lactate similar to *Cr*GlcDH protein (Figure 15). However, no activity was observed for *Dv*DLDH when glycolate was used as a substrate.

Figure 15. Comparison of substrate specificity of *Cr*GlcDH and its nearest proteobacterial homologue (*Dv*DLDH). Recombinant proteins were purified by affinity chromatography and tested with glycolate and D -lactate as substrates. Data points represent mean \pm SE of three independent replicates.

RESULTS

3.1.7. The effect of temperature and pH on the activity of purified *CrGlcDH*

The effect of the temperature on enzyme activity was measured in the temperature range of 4–50 °C at pH 8 using 100mM sodium phosphate buffer. The effect of pH on the activity was measured at 30°C within pH range of 6-9 using 100mM of sodium phosphate buffer. The optimum temperature for the reaction with glycolate as a substrate was determined to 30°C and the optimum pH to 8.0 (Figure 16). These parameters were used for the further analysis.

Figure 16. Effect of temperature and pH on the catalytic activity of recombinant *CrGlcDH* protein. *CrGlcDH*-His was purified from overexpressing bacteria and glycolate dehydrogenase activity was assayed at different temperatures (A) or different pH (B). Data points represent mean \pm SE of three independent replicates.

3.1.8. Co-factor analysis of recombinant *CrGlcDH*

The co-factor preference of the partially purified *CrGlcDH* was analyzed by measuring the extinction due to formation of glyoxylate-phenylhydrazine at 324nm as described by Lord (1971) (See 2.2.2.8). Activity of *CrGlcDH* with glycolate as a substrate was only detected with DCIP and/or PMS as co-factors. Neither flavine nucleotides (FMN, FAD), nor nicotineamide dinucleotides (NAD^+ , NADP^+) were accepted. Furthermore, there was no activity with molecular oxygen or oxidized cytochrome c as electron acceptors (Table 16).

RESULTS

Table 16. Electron acceptor specificity of the recombinant *CrGlcDH* relative to DCIP reduction. Data points represent mean \pm SE of three independent replicates. *different assay (See 2.2.2.8).

Electron acceptor	Relative specific activity (% of DCIP)
O ₂	0
DCIP	100 \pm 0.02
PMS	93 \pm 3.41
DCIP+PMS	127 \pm 3.87
FAD	0
FMN	0
NAD ⁺	0
NADP ⁺	0
Cytochrome C*	0

3.1.9. Determination of kinetic properties of the recombinant *CrGlcDH*

Kinetic parameters (Table 17) were determined for glycolate and the two lactate enantiomers as was described in 2.2.2.8. The partially purified *CrGlcDH* enzyme showed high affinity to glycolate with a K_m value of 200 μ M and a catalytic rate of 116 min⁻¹. The resulting catalytic efficiency (K_{cat}/K_m) was 655min⁻¹ mM⁻¹. Similarly, the kinetic properties for *CrGlcDH* using D-lactate were very close to that with glycolate. The K_m value for D-lactate was 450 μ M, and the catalytic rate was 324min⁻¹. Furthermore, the catalytic efficiency (K_{cat}/K_m) for D-lactate was very close to that for glycolate, it was determined to be 781min⁻¹mM⁻¹. In contrast, with L-lactate, the K_m value was almost 100-fold higher than for glycolate, and the catalytic rate was reduced by 2-fold. This resulted in a very low catalytic efficiency with L-lactate as a substrate.

RESULTS

Table 17. Kinetic parameters of recombinant *CrGlcDH*. Kinetic data were best fit by non-linear regression analysis. Parameters represent mean \pm SE of three independent enzyme preparations.

	K_m (mM)	K_{cat} (min ⁻¹)	K_{cat}/K_m (min ⁻¹ mM ⁻¹)
Glycolate	0.21 \pm 0.06	116 \pm 7	655
D-lactate	0.45 \pm 0.1	325 \pm 17	781
L-lactate	19 \pm 1.3	92 \pm 27	5

3.1.10. Effect of different inhibitors on *CrGlcDH* activity

The enzymatic activity of purified *CrGlcDH* was tested in presence of different potential inhibitors using glycolate as a substrate and DCIP as an electron acceptor as was described in (2.2.2.8). EDTA showed almost no inhibitory effect on *CrGlcDH* activity even at high concentrations. However, CuSO₄ inhibited activity already at moderate concentrations (0.1mM) providing evidence that disulfide bonds are required for protein activity. KCN sensitivity is another joint property of GlcDH enzymes (Bari et al., 2004). *CrGlcDH* activity was inhibited by KCN in a concentration dependent manner (Table 18).

Table 18. Effect of inhibitors on the activity of recombinant *CrGlcDH*. Data represent mean \pm SE of three independent replicates.

Inhibitors	Concentration (mM)	Inhibition (%)
EDTA	1	6 \pm 3.75
	10	8 \pm 6.05
CuSO ₄	0.1	28 \pm 4.91
	0.5	95 \pm 4.74
	2	100 \pm 0.06
KCN	0.1	31 \pm 1.89
	0.5	98 \pm 0.77
	2	100 \pm 0.01

RESULTS

3.1.11. Mutational analysis of the glcF homology domain

In order to understand the importance of the GlcF-homology region in the C-terminus of the *CrGlcDH* protein for catalytic activity, a deletion mutant and two point mutations were generated. The truncated *CrGlcDH* gene (*CrGlcDH*ΔC660) and the two substitution mutations were cloned into pET22 vector and overexpressed in *E.coli* BL21 codon plus (Figure 8). The enzymatic activities of *CrGlcDH* and the three different mutants were determined with crude protein extracts, but an extract from *E. coli* transformed with the empty vector was always used as a negative control (Figure 17 & 18). Deletion of the GlcF homology region resulted in a complete loss of *CrGlcDH* activity in this assay. Furthermore, substituting of 3 or 4 cysteine residues (673, 676, 679, and 683) with serine residues in a putative 4Fe-4S (aa 673-683) cluster in GlcF-homology region resulted in loss of activity. These results indicate the importance of this region for *CrGlcDH* activity.

Figure 17. Enzymatic properties of different *CrGlcDH* mutants. Protein extracts were used to compare the enzymatic activity of *CrGlcDH* and the three different mutants. Columns represent mean \pm SE of three independent replicates. NC, empty vector control. Mut1/Mut2, *CrGlcDH*-His constructs with cysteine to serine mutations as indicated in the figure 17A. Delta C, *CrGlcDH*-His construct truncated at amino acid position 660.

RESULTS

Figure 18. Overexpression of *CrGlcDH* and its mutants. A, Coomassie stained SDS-PAGE. B, Western blot of the SDS gel using anti-His antibodies. Lane 1, protein marker. Lane 2, *CrGlcDH*-His. Lane 3, mutant 1. Lane 4, mutant2. Lane 5, delta C. Equal amount from the soluble protein extract of each contract was loaded.

RESULTS

3.2. Simultaneous overexpression of cyanidase and formate dehydrogenase in *Arabidopsis thaliana* chloroplasts enhanced cyanide metabolism and cyanide tolerance

I wanted to test whether overexpression of cyanidase (CYND, from *Pseudomonas stutzeri*) could confer enhanced cyanide resistance to plants and whether formate resulting from the reaction could be further converted to CO₂ by formate dehydrogenase (FDH, from *Arabidopsis thaliana*). Before transfer to plants, the activity of both enzymes was tested in crude extracts from bacteria overexpressing the respective cDNA (This part was done by Dr. Rashad Kebeish, Zagazig University /Egypt). Clear increases in activity relative to the empty vector controls could be observed for both enzymes in specific assays.

3.2.1. Generation of CYND and FDH transgenic *Arabidopsis* plants

The genes were transferred separately (CYND, FDH) or in combination (CYND+FDH) to *Arabidopsis* plants. The enzymes were constitutively expressed, but targeted to chloroplasts to make best potential use of CO₂ resulting from the combined reactions of CYND and FDH. Transgenic lines were selected based on kanamycin resistance. Transgenes expression was initially tested by quantitative PCR in the CNYD+FDH lines. As shown in Figure 19A, three independent lines were selected. Lines CYND+FDH-4 and CYND+FDH-6 showed higher expression of both transgenes compared to line CYND+FDH-2. Expression of CYND in transgenic plants was also determined on the protein level by using an antibody specific for the His-tag. A strong signal at the expected molecular weight for CYND protein of around 44kDa was detected (Figure 19B&C). In addition, the activity of CYND and FDH was tested in extracts from chloroplasts isolated from CYND+FDH plants (This part was done by Dr. Rashad Kebeish, Zagazig University /Egypt).

RESULTS

Figure 19. Characterization of FDH and CYND enzymes used in this study. A, Amount of FDH (black bars) and CYND (gray bars) transcripts relative to actin2 transcripts in three independent Arabidopsis lines overexpressing the FDH+CYND construct. Samples were collected from the youngest fully expanded leaf 6h after onset of light. B, Coomassie stained SDS-PAGE of the total protein extract from Arabidopsis plants. C, Western blot of the SDS gel using anti-His antibodies. Lane 1, protein marker. Lane 2, azygous plants. Lane 3, FDH+CYND-2 line. Lane 4, FDH+CYND-4 line. Lane 5, FDH+CYND-6 line. Equal amount of proteins were loaded.

3.2.2. Analysis of the performance of transgenic plants under different cyanide stress conditions

I) Performance of transgenic plants on MS/KCN plates

Plants were germinated on vertical MS/agar plates containing 250 μ M KCN (See 2.2.3.7). The root length was measured after two weeks. A pool of azygous plants derived from the same mother plant was used as the control. In each plate, both the transgenic and azygous plants were represented. Average root length was significantly increased from 1.6 to 2.5cm (+56%) in CYND+FDH plants compared to controls. However, root length was almost identical for both genotypes in the absence of KCN.

RESULTS

Figure 20. Growth of transgenic Arabidopsis plants and controls on vertical agar plates (A&B) containing 250 μ M KCN (+KCN) or not (-KCN). Azygous: Segregants from FDH+CYND plants that lost the transgene; FDH+CYND-4: Plant line transgenic for formate dehydrogenase and cyanidase. Data are means of three independent experiments each with at least ten plants per genotype \pm SE. Asterisks represent statistically significant differences compared to azygous control plants (* = $p < 0.05$, ** = $p < 0.01$, *** = $p < 0.001$).

II) Performance of the transgenic plants in hydroponic systems

Arabidopsis plants were grown in hydroponics for two weeks without KCN and then KCN was added for two weeks or not (See 2.2.3.7). Rosette diameter and fw were used as indicators for KCN resistance. CYND+FDH plants and controls showed very similar growth when KCN was omitted from the medium. However, KCN addition resulted in a reduction of both rosette diameter and fw (Figure 21 A, B and C) by approximately 30% relative to untreated plants in the azygous control line. In contrast, the CYND+FDH line was hardly affected under these conditions (+ 3% for fw and -10% for diameter).

RESULTS

Figure 21. Growth of transgenic Arabidopsis plants and controls in hydroponic systems (A, B and C). Azygous: Segregants from FDH+CYND plants that lost the transgene; FDH+CYND-4: Plant line transgenic for formate dehydrogenase and cyanidase. Data are means of three independent experiments each with at least six plants per genotype \pm SE. Asterisks represent statistically significant differences compared to azygous control plants (* = $p < 0.05$, ** = $p < 0.01$, *** = $p < 0.001$).

III) Performance of transgenic plants grown in sand

As further analysis of the synthetic pathway, I grew the transgenic plants in sand supplemented with MS medium for four weeks and then MS/500 μ M KCN was applied for another two weeks (See 2.2.3.7). The rosette diameter and fresh weight were recorded (Figure 22). No differences were observed between the genotypes in the -KCN controls. Addition of KCN reduced rosette diameter by 30% and fw by 50% in the control. In the CYND+FDH line, diameter and fw were both only reduced by 17% when compared to untreated plants. These assays provided independent evidence that CYND+FDH double overexpressors performed superior when KCN was supplied via the root system.

RESULTS

Figure 22. Growth of transgenic Arabidopsis plants and controls in sand (A, B and C). Azygous: Segregants from FDH+CYND plants that lost the transgene; FDH+CYND-4: Plant line transgenic for formate dehydrogenase and cyanidase. Data are means of three independent experiments each with at least six plants per genotype \pm SE. Asterisks represent statistically significant differences compared to azygous control plants (* = $p < 0.05$, ** = $p < 0.01$, *** = $p < 0.001$).

IV) Gas exchange measurements

In order to study the potential physiological effect of the established pathway, gas exchange characteristics of CYND+FDH and control lines were determined after two weeks of KCN treatment. In parallel, plants were grown without KCN treatment and tested (Table 19). As observed before in growth assays, CYND+FDH plants and control plants performed very similar under non-stressed conditions (-KCN). KCN treatment reduced CO_2 assimilation rate by 14% in the control whereas CYND+FDH plants remained unaffected. Similar trends were observed for transpiration (-14% for control vs. +7% for CYND+FDH) and stomatal conductance (-14% for control vs. +10% for CYND+FDH). Interestingly, leaf internal CO_2 concentration was largely unaffected in control plants by the treatment, but significantly increased in CYND+FDH plants by 10%. These data suggest that leaf internal CO_2 might be enhanced in CYND+FDH plants by CO_2 release from KCN.

RESULTS

Table 19. Gas exchange measurements of transgenic lines and azygous controls in the presence and absence of KCN (means derived from at least six independent plants \pm SE).

	-KCN		+KCN	
	Azygous	FDH+CYND-4	Azygous	FDH+CYND-4
Assimilation rate ($\mu\text{mol CO}_2 \text{ m}^{-2}\text{s}^{-1}$)	15.11 (\pm 0.58)	15.39 (\pm 0.35)	13.01 (\pm 0.5)	15.76 (\pm 0.55)**
Internal CO ₂ concentration (C_i) ($\mu\text{mol m}^{-2}\text{s}^{-1}$)	211.31 (\pm 9.2)	217.76 (\pm 5.7)	201.41 (\pm 7.9)	237.23 (\pm 4.0)***
Stomatal Conductance ($\text{mol H}_2\text{O m}^{-2}\text{s}^{-1}$)	0.152 (\pm 0.016)	0.164 (\pm 0.011)	0.130 (\pm 0.012)	0.149 (\pm 0.013)
Transpiration ($\text{mol H}_2\text{O m}^{-2}\text{s}^{-1}$)	1.81 (\pm 0.19)	1.93 (\pm 0.12)	1.56 (\pm 0.15)	1.78 (\pm 0.16)

* = $p < 0.05$, ** = $p < 0.01$, *** = $p < 0.001$ relative to azygous control.

4. Discussion

The goal of this study was to provide additional methods to enhance plant tolerance to abiotic stresses. Two different approaches were carried out during this study. The first objective was to improve the photorespiration cycle that is now known to be an important part in stress response in green tissues to prevent ROS accumulation and protect photosynthesis from photoinhibition (Voss et al., 2013). Photorespiration was reported to increase under abiotic stresses (Miller et al., 2010b). Several attempts were reported in the past few years to manipulate the photorespiration pathway to save CO₂, NH₃ and energy (Kebeish et al., 2007; Andersson, 2008; Carvalho et al., 2011; Maier et al., 2012). Kebeish et al. (2007) established a chloroplastic pathway in *Arabidopsis* plants aiming to improve photorespiration and provide CO₂ in the vicinity of Rubisco. In that pathway a bacterial GlcDH consisting of three functional genes was used to oxidize glycolate. In this study, I introduced a new GlcDH candidate from *Chlamydomonas* consisting of a single gene that could replace the three genes in the Kebeish et al (2007) bypass.

The second objective was to introduce a novel pathway into *Arabidopsis* plants to improve cyanide detoxification. The cyanide was reported to be biosynthesized as a co-product of ethylene and can increase under certain conditions such as abiotic stresses (Tittle et al., 1990) that could be a threat to the plants. Introduction of an efficient pathway to enhance cyanide detoxification and assimilation could have advantages for crop improvement.

4.1. Biochemistry and physiological relevance of GlcDH enzymes

When comparing enzymatic properties of the *Cr*GlcDH recombinant enzyme in this study to those reported previously for a *Chlamydomonas* protein fraction containing GlcDH activity (Nelson and Tolbert, 1970), multiple similarities were observed indicating that *Cr*GlcDH is indeed the enzyme that was enzymatically described in the previous study. The K_m for glycolate was almost identical, whereas the K_m for D-lactate was slightly lower for the recombinant enzyme compared to the enriched fraction (Table 17). The pH optimum was in the slightly alkaline range in both studies (Figure 13) and the degree of inhibition by various inhibitors (Table 18) was very much comparable. Specifically, both the recombinant enzyme and the enriched fraction only showed enzymatic activity with artificial electron acceptors, but not with any of the tested naturally occurring electron acceptors (Table 16). It has been shown for several chlorophytes green algae that mitochondrial GlcDH activity *in vivo* is linked to O₂ consumption

DISCUSSION

via the mitochondrial electron transport chain (METC) (Paul et al., 1975; Stabenau and Winkler, 2005). Moreover, both in chlorophytes (Beezley et al., 1976) and *E. coli* (Sallal and Nimer, 1989), GlcDH activity has been shown to be associated with membranes by cytochemical assays or subcellular fractionation, respectively. Membrane association is also in agreement with the low solubility of the recombinant protein in our assays (data not shown). Therefore I suggest that CrGlcDH is a membrane-bound mitochondrial enzyme that feeds electrons from oxidation of glycolate into the METC.

Consistent with this hypothesis, mutational analyses of a potential Fe-S-cluster in the C-terminal GlcF-homology region indicate an important function of this domain in electron transport (Figure 14). However, there are conflicting data in the literature concerning the strict requirement of GlcF or a GlcF-homology region for GlcDH activity. A *glcF* knockout in *E. coli* resulted in a complete loss of GlcDH activity in protein extracts (Pellicer et al., 1996). On the other hand, the recombinantly expressed GlcD protein from *Synechocystis* showed GlcDH activity (Eisenhut et al., 2006). Previous studies provided physiological evidence that a GlcD homologue in higher plant mitochondria (encoded by At5g06580, Bari et al., 2004; Niessen et al., 2007, 2012) oxidizes glycolate to glyoxylate. This enzyme also does not contain a GlcF homology domain and was suggested to oxidize glycolate in parallel to the peroxisomal GOX that is typical for plants. However, a recent enzymatic characterization revealed that the recombinant enzyme showed much higher activity with D-lactate compared to glycolate as a substrate questioning its role in glycolate metabolism and suggesting a function in the methylglyoxal pathway (Engqvist et al., 2009). Side-by-side activity assays with proteins from different sources would be required to conclusively judge about the role of the GlcF domain in function of GlcDH enzymes from different sources.

Why do different clades use different enzymes for glycolate oxidation? Table 20 provides a comparison with data from selected previous studies on GOX and GlcDH enzymes. The most evident difference between the enzymes is the lower specific activity of GlcDH compared to GOX enzymes. The recruitment of GOX into photorespiration might therefore be a consequence of the much higher flux rates through photorespiration in most land plants compared to aquatic photosynthetic organisms that express carbon concentrating mechanisms (Raven et al., 2008; Wang et al., 2011; Price et al., 2013).

4.2. Evolution of glycolate dehydrogenases

CrGlcDH was originally identified in a mutant screen in *Chlamydomonas* and suggested to encode a GlcDH based on its homology to GlcD and GlcF from *E. coli* (Nakamura et al., 2005). However, when searching nearest homologues to *CrGlcDH* in the available sequence information, another so far biochemically uncharacterized group of enzymes from proteobacteria was identified as the nearest homology group (Figure 11). There was not obvious homology to GlcE, the third subunit of *EcGlcDH*, in any of these proteins, although GlcE has been shown to be essential for activity of the 3-subunit GlcDH enzymes by mutant analyses in *E. coli* (Pellicer et al., 1996). The tested proteobacteria containing a *CrGlcDH* homologue still in addition contained the *glc* operon with separated GlcD, GlcE and GlcF subunits. Consistent with this observation, the nearest homologue from *Desulfovibrio* did not accept glycolate as a substrate (Figure 18). Thus, enzymes of the *CrGlcDH* homology group probably only evolved specificity for glycolate as a substrate in chlorophytes.

There is no simple explanation for the appearance of *CrGlcDH* homologues in only two evolutionary widely separated lineages. Mitochondria and some alpha-proteobacteria share a common ancestor (Richards and Archibald, 2011). The gene might therefore have been transferred during mitochondrial endosymbiosis. This is consistent with the mitochondrial localization of *CrGlcDH* (Beezley et al., 1976; Nakamura et al., 2005). However, this scenario would imply that the homologue was lost in most eukaryotic lineages after mitochondrial endosymbiosis. Thus, the more parsimonious explanation for the observed clustering is that *CrGlcDH* homologues in chlorophytes and proteobacteria evolved independently and might serve different functions in lactate and glycolate metabolism, respectively.

DISCUSSION

Table 20. Comparison of specific activities of GlcDH and GOX from different organisms.

Enzyme	Organism	Specific activity ($\mu\text{mol min}^{-1} \text{mg}^{-1}$)	K_m values (for glycolate, mM)	Reference
GlcDH	<i>E.coli</i> extract	0.14-3.1	0.04	Lord et al (1971)
GlcDH	<i>Chlamydomonas</i> (<i>E. coli</i> derived)	1	0.21	This publication
GOX	Pea leaf extract	30	0.25	Kerr and Groves (1975)
GOX	Spinach (<i>E.coli</i> derived)	26	0.2	Macheroux et al (1992)

4.3. Establishment of a novel pathway in *Arabidopsis thaliana* for cyanide detoxification

In this study I tested an approach for the enhancement of cyanide tolerance in plants. The introduced pathway is synthetic, since it combines bacterial and plant elements (CYND and FDH; respectively). The used cyanidase (CYND) enzyme in this study was derived from *Pseudomonas stutzeri* AK61. The enzyme was previously characterized and its catalytic properties were reported (Watanabe et al., 1998). Furthermore, formate dehydrogenase (FDH) was derived from *Arabidopsis thaliana*. Combination of both enzymes would result in complete oxidation of cyanide to NH_3 (resulting from the CYND reaction) and CO_2 (resulting from the FDH reaction). This was not further enhanced by simultaneous expression of FDH as expected. CO_2 release from formate is difficult to measure because of the refixation of CO_2 in the chloroplast by photosynthesis. However, gas exchange measurements data indicated that leaf internal CO_2 was enhanced in CYND+FDH plants and that this effect was dependent on KCN application. This suggested that both enzymes cooperate *in planta* in the decomposition of cyanide to two gases that are both useful substrates for plant biosynthesis.

Photosynthetic measurements indicated that FDH is important for CO_2 production from cyanide in the leaf. An alternative interpretation of the importance of FDH in the synthetic detoxification pathway would be that FDH simply removed toxic formate resulting from the CYND reaction

that might otherwise accumulate. Formate is a natural endogenous compound in plants resulting from non-enzymatic decarboxylation of photorespiratory glyoxylate in peroxisomes (Wingler et al., 2000). It can be used as a C1-donor (Wingler et al., 2000) or can be oxidized by the endogenous formate dehydrogenase that is mainly targeted to mitochondria (Hourton-Cabassa et al., 1998) (although dual targeting to mitochondria and chloroplasts has been reported for *Arabidopsis* (Herman et al., 2002)). There are different reports about the impact of externally applied formate on plants. Whereas low amounts of formate in the growth substrate might even promote growth (Shiraishi et al., 2000), higher concentrations delay germination or affect plant growth (Li et al., 2002; Himanen et al., 2012). Consequently, FDH overexpression protected plants from formate toxicity (Li et al., 2002). This detoxification of excess formate might be also the major function of FDH in our synthetic cyanide degradation pathway.

4.4. Influence of the synthetic pathway on plant resistance to cyanide

Soil contamination is the major source of cyanide toxicity to plants (Trapp et al., 2003). Noteworthy, a significant amount of exogenously applied cyanide is not metabolized in roots, but ends up in shoots (Yu et al., 2012). I used three different methods to test resistance of CYND+FDH plants to cyanide contamination of growth substrates (See 2.2.3.7). In all these assays, CYND+FDH plants performed significantly better than controls and this effect was always dependent on cyanide application indicating that the observed phenotype is not due to any secondary effect of transgene overexpression on growth. Thus, CYND+FDH plants might be suitable for detoxification of soils containing increased amounts of cyanides that are not tolerated by other plants. For example, willow trees can detoxify up to 10 mg cyanide per kg fw, but rapidly die at concentrations of > 2 mM (Larsen and Trapp, 2006). *Sorghum bicolor* can even survive such concentrations in the growth substrate by degrading cyanide that was uptaken (Trapp et al., 2003). Seedlings of the model plant *Arabidopsis* are sensitive to cyanides and show growth defects even when exposed to concentrations around 50-100 μ M of cyanide (García et al., 2010; McMahon Smith and Arteca, 2000; O'Leary et al., 2014). In contrast, CYND+FDH plants survived concentrations up to 300 μ M without visible signs of stress. It remains to be shown in further studies whether this approach is also effective in other species that have higher capacities for endogenous cyanide metabolism.

DISCUSSION

It is useful to compare observed effects of CYND+FDH overexpression to another recently published transgenic approach towards enhanced cyanide resistance of *Arabidopsis* that was based on enhancing the endogenous pathway for cyanide detoxification (O'Leary et al., 2014) through boosting the downstream flux of cyanide to asparagine. O'Leary et al (2014) overexpressed the *Pseudomonas fluorescens* β -cyanoalanine nitrilase pinA in *Arabidopsis* plants. PinA enzyme is a downstream enzyme in the cyanide assimilation pathway that metabolizes the toxic β -cyanoalanine compound that results from the incorporation of cyanide and cysteine by catalysis of the mitochondrial β -cyanoalanine synthase (CAS) enzyme. Plant growth analyses in this study were focused on seedlings grown on agar plates containing 50 μ M KCN and are, thus, best compared to the root length data shown in Figure 20 (250 μ M cyanide in agar plates). In both studies, root growth was reduced by approximately 50% after cyanide treatment in the WT, but fully restored by the transgenic intervention. Whereas carbon and nitrogen from cyanide was assimilated via formation of the amino acid asparagine in the endogenous pathway, the synthetic pathway released gaseous NH₃ and CO₂ that were probably re-assimilated by plant primary carbon and nitrogen assimilation pathways. Additional energy and reducing power would be required for re-fixation via gaseous intermediates (Peterhansel et al., 2010) compared to direct formation of amino acids. Together, these results indicate that both boosting the endogenous pathway and addition of a synthetic pathway were instrumental in enhancing cyanide resistance. It would be interesting to see whether both approaches can additively enhance cyanide metabolism in plants and facilitate the use of plants in bioremediation of toxic cyanide contaminations.

5. Conclusion

Overall most of the goals were fulfilled by this study: CrGlcDH protein from *Chlamydomonas reinhardtii* was recombinantly overexpressed successfully purified and its enzymatic properties were studied. This protein was confirmed to be a glycolate dehydrogenase enzyme using both glycolate and D-lactate as substrates, a typical feature of GlcDH enzymes. Additional mutational experiments would be interesting to identify the active site of this enzyme and figure out the evolutionary role of different amino acids controlling substrate specificity.

In addition, the second goal was also achieved: a new pathway for cyanide detoxification was established in *Arabidopsis thaliana*. The results showed that the pathway was effective in cyanide detoxification under tested conditions in this study. The results are still preliminary and additional studies might be required to test this pathway in other plants and under different conditions. Comparing this synthetic pathway with other plants that have reported to normally detoxify cyanide would be interesting experiments to see how efficient is the synthetic pathway described in this study.

APPENDIX

S3. Evolutionary relationships of *C7*GlcDH using neighbor-joining method. Bootstrap values (%) are for 500 replicates. Evolutionary distances were computed using the p-distance method. Sequence alignment and evolutionary analyses were conducted in MEGA5.1 software. *Arabidopsis thaliana* GOX was used as an outgroup. Numbers in parentheses are Genbank accession numbers.

6.2. List of abbreviations

Abbreviation	Full form
Amp	Ampicillin
APS	Ammonium persulfate
Asn	Asparagine
<i>A. thaliana</i>	<i>Arabidopsis thaliana</i>
GlcDH	Glycolate dehydrogenase
ATP	Adenosine triphosphate
bla	β --lactamase gene for selection in bacteria (ampicillin/carbenicillin resistance).
bps	Base pairs
BSA	Bovine serum albumin
C ₂ -cycle	Photorespiratory cycle
C ₃ -cycle	Benson Calvin cycle
CAT	Catalase
Carb	Carbenicillin
cDNA	Complementary DNA
Ci	The internal CO ₂ concentration inside plant leaf
CO ₂	Carbon dioxide
CrGlcDH	<i>Clamydomonas reinhardii</i> glycolate dehydrogenase
CYND	<i>Pseudomonas stutzeri</i> AK61 cyanindase
DCIP	2,6 dichlorophenolindophenol sodium salt
D-LDH	D(+)-lactate dehydrogenase
DNA	Deoxyribonucleic acid
dNTP	Deoxyribonucleoside triphosphate
DTT	Dithiothreitol
DvDIDH	<i>Desulfovibrio vulgaris</i> D.lactate dehydrogenase
DW	Dry weight
EcGlcDH	<i>E. coli</i> glycolate dehydrogenase
EDTA	Ethylene diamine tetra acetic acid

APPENDIX

FW	Fresh weight
G3P	Glyceraldehyde-3-phosphate
GC/MS	Gas Chromatography/Mass Spectrometry
GDC	Glycine decarboxylase
GDC/SHMT	Glycine decarboxylase/serine hydroxymethyl transferase
GST	Glutathione S-transferase fusion protein
GK	Glycerate kinase
<i>GlcD</i>	Coding sequence for the D subunit of glycolate dehydrogenase in <i>E. coli</i>
<i>GlcE</i>	Coding sequence for the E subunit of glycolate dehydrogenase in <i>E. coli</i>
<i>GlcF</i>	Coding sequence for the F subunit of glycolate dehydrogenase in <i>E. coli</i>
GOGAT	Glutamate:glyoxylate aminotransferase
GOX	Glycolate oxidase
GS	Glutamine synthetase
h	Hour
Hepes	N-2-hydroxyethylpiperazine-N'-2-ethanesulfonic acid
His	The coding sequence for His-tag protein
HPR	Hydroxypyruvate reductase
IPTG	Isopropyl- β -D-thiogalactoside
Kan	Kanamycin
kDa	Kilodalton
Km	Michaelis constant
LB medium	Luria Bertani medium
MBP	Maltose binding protein fusion tag
mg	Milligram
min	Minute
mM	Milli mol
ml	Milli liter
mRNA	Messenger RNA
MS medium	Murashige and Skoog Basal medium
mTP	Mitochondrial targeting peptide

APPENDIX

μg	Microgram
μl	Micro liter
μM	Micro mol
NAD ⁺ /NADH	Nicotinamide adenine dinucleotide (oxidized/reduced form)
NADP ⁺ /NADPH	Nicotinamide adenine dinucleotide phosphate (oxidized/reduced form)
OD	Optical density
ON	overnight
p35SS/pA35S	Promotor (duplication) and polyadenylation-/termination sequence from CaMV
PAnos	Polyadenylation promoter of nopaline synthetase gene from <i>A. tumefaciens</i>
PCR	Polymerase chain reaction
PCR-cycle	Photosynthetic carbon reduction cycle
PG	Phosphoglycolate
PGA	Phosphoglycerate
PGP	Phosphoglycolate phosphatase
PMS	Phenazine methosulfate
Pnos	Promoter of nopaline synthase gene from <i>A. tumefaciens</i> .
PYR	Pyruvate
Rif	Rifampicin
RNA	Ribonucleic acid
rpm	Rotation per minute
RT	Room temperature
RT	Reverse transcriptase
RT-PCR	Reverse transcriptase-polymerase chain reaction
Rubisco	Ribulose 1,5 bisphosphate carboxylase/oxygenase
RuBP	Ribulose 1, 5 bisphosphate
SDS-PAGE	Sodium dodecyl sulphate-polyacrylamide gel electrophoresis
sec	Second
SE	Standard error
SGAT	Serine:glutamate aminotransferase

APPENDIX

TAE	Tris-acetate-EDTA-buffer
TEMED	N, N, N', N'-tetramethyl ethylene diamine
Tris	Tris-acetate-EDTA-buffer
UV	Ultraviolet
x	Times
xg	Apparent gravity
Y(II)	photosynthetic yield
v/v	Volume per volume
w/v	Weight per volume
WT	Wild type

6.3. List of figures

Figure no.	Name	Page
Figure 1	Schematic diagram for the transfer of electrons and protons in the thylakoid membrane.....	2
Figure 2	Schematic overview of the bi-functions (CO ₂ /O ₂ fixation) of Rubisco in photosynthetic organisms.....	3
Figure 3	The carbon reactions pathway in C ₃ plants (Calvin cycle).....	3
Figure 4	The major photorespiratory pathway.....	7
Figure 5	A scheme describing the different routes for PG metabolism in <i>Synechocystis sp.</i>	9
Figure 6	Scheme of the original photorespiration pathway.....	12
Figure 7	Markers used throughout this work for gel-electrophoresis.....	23
Figure 8	Structure of different plasmids constructed during this study.....	32
Figure 9	Schematic drawing of indicated tank- blotting methods.....	41
Figure 10	Floral dip Agrobacterium mediated transformation of Arabidopsis plants.....	45
Figure 11	Evolutionary relationship of C7GlcDH using neighbor-joining method.....	48

APPENDIX

Figure 12	Alignment of <i>CrGlcDH</i> against a putative D -lactate dehydrogenase from <i>Desulfovibrio vulgaris</i> (<i>DvDLDH</i>).....	49
Figure 13	Purification of <i>CrGlcDH</i> -His using Ni^{2+} -NTA affinity chromatography.....	51
Figure 14	Purification of <i>DvDLDH</i> -His using Ni^{2+} -NTA affinity chromatography.....	52
Figure 15	Comparison of substrate specificity of <i>CrGlcDH</i> and its nearest proteobacterial homologue (<i>DvDLDH</i>).....	53
Figure 16	Effect of temperature and pH on the catalytic activity of recombinant <i>CrGlcDH</i> protein.....	54
Figure 17	Enzymatic properties of different <i>CrGlcDH</i> mutants.....	57
Figure 18	Overexpression of <i>CrGlcDH</i> and its mutants.....	58
Figure 19	Characterization of FDH and CYND enzymes used in this study.....	60
Figure 20	Growth of transgenic <i>Arabidopsis</i> plants and controls on vertical agar plates....	61
Figure 21	Growth of transgenic plants and in hydroponic systems.....	62
Figure 22	Growth of transgenic <i>Arabidopsis</i> plants and controls in sand.....	63

6.4. List of tables

Table No.	Name	Page
Table 1	Comparison of the enzymatic reactions of photorespiration and the three bypasses.	13
Table 2	Different bacterial strains used throughout this study.....	16
Table 3	Instruments and equipments used in this study.....	18
Table 4	Specific chemicals used throughout this study.....	19
Table 5	DNA and protein markers used throughout this study.....	20
Table 6	Reaction kits used throughout this study.....	20
Table 7	List of enzymes used throughout this study.....	21
Table 8	Different synthetic oligonucleotides used throughout this study.....	22
Table 9	List of buffers and media used during the present work.....	24
Table 10	List of plasmids generated in course of this study.....	28
Table 11	Software and internet-programs used throughout this study.....	30
Table 12	PCR reaction mixture.....	32
Table 13	Standard PCR conditions.....	32
Table 14	RT reaction mix.....	34
Table 15	Substrate specificity of recombinant <i>CrGlcDH</i>	47
Table 16	Electron acceptor specificity of the recombinant <i>CrGlcDH</i> relative to DCIP reduction.....	49
Table 17	Kinetic parameters of recombinant <i>CrGlcDH</i>	50
Table 18	Effect of inhibitors on the activity of recombinant <i>CrGlcDH</i>	50
Table 19	Gas exchange measurements of transgenic lines and azygous controls in the presence and absence of KCN.....	63
Table 20	Comparison of specific activities of GlcDH and GOX from different organisms....	62

6.6. Curriculum vitae

Personal information

Name: Mohamed Hassan Mohamed Ahmed Aboelmy

Date of birth: 13.06.1979

Place of birth: Menia

Nationality: Egyptian

Marital status: Married

Educational data:

1985-1990 Shem primary school (excellent grade) - Menia/Egypt

1990-1993 Shem prep school (excellent grade) - Menia/Egypt

1993-1995 Maghagha secondary school (very good grade) - Menia/Egypt

1996-2000 Bachelor science (Very good grade) - Faculty of science/ Minia University
- Menia/Egypt

2003 Diploma in Microbiology (very good grade) – Institute botany South of
Valley University, Sohag, Egypt

2009 International Master of Horticulture (plant Biotechnology): Gottfried
Wilhelm Leibniz University Hannover, Germany

Since November 2009 PhD student at the Leibniz University Hannover, Institute of Botany,
Christoph Peterhänsel;

Research associate at the Leibniz University Hannover, Institute of Botany,
Prof. Dr. Christoph Peterhänsel

6.7. Acknowledgements

First and foremost I am grateful to Professor Dr. Christoph Peterhänsel for giving me the chance to work in his laboratory. I am also very thankful for his supervision, his friendship and his hospitality. The critical reading, discussion and correction of this manuscript by him made it possible for me to present this manuscript in its present form.

I would wish to express my special thanks to Prof. Dr. Bernhard Huchzermeyer, Prof. Dr. Jutta Papenbrock and Prof. Dr. Sascha Offermann and other members of Botany Institute for their kindness and cooperation.

I wish to introduce my special thanks to member of AG Peterhänsel for their friendship and their endless help during my work.

I also would like to thank Prof. Dr. Hans Peter Braun for helping with mass spectrometry work.

My special thanks to the Egyptian government for financing my study in Germany from 2007 to 2012. I also thank the Institute for Botany - Hannover University for financing my study from 2012 till the end of this study.

My special thanks to my family and my children Rofida, Rahaf and Retal for their lovely smiles that always refresh my life

6.8. Declaration / Erklärung

Herewith I declare that I have written this PhD thesis myself, using only the referenced literature.

Hiermit versichere ich, dass ich die vorliegende Doktorarbeit selbstständig verfasst und keine anderen als die angegebenen Hilfsmittel und Quellen verwendet habe.

Mohamed H Aboelmy

Hannover, 2014
